Cone-beam image reconstruction by moving frames

Xiaochun Yang, Biovisum, Inc. Berthold K.P. Horn, MIT CSAIL

Cone-beam Imaging Apparatus

- Radiation source and area detector
- Source-detector rotate around the object
- Collect integrals of density along straight lines when source travels along a 3D curve

The problem

Cone-beam reconstruction:

to recover a 3D density function from its integrals along a set of lines emitting from a 3D curve

Among the first problems in integral geometry

Difficulties

- Inverse calculation deals with curved spaces
- Algorithmic implementation encounters: Large dataset
 - sophisticated geometric mapping
 - expensive data interpolations

Radon's formula

 $d\beta$

 $-x \cdot \beta$

- Radon transform: integral over planes $Rf(l,\beta) := \int_{x \in \{x | x \cdot \beta = l\}} f(x) dx$
- 3D Radon inverse (1917):

$$f(x) = -\frac{1}{8\pi} \int_{S^2} \frac{\partial^2 R f(l,\beta)}{\partial l^2} \bigg|_{l=0}^{2}$$

Backprojection sphere

Grangeat's "Fundamental Relation"

 Link cone-beam data to the first-order radial derivative of the Radon transform (1991)

Geometric constraints: within and across projections

3D to 2D reduction

 Great circle under a rigid rotation

X. Yang: Geometry of Cone-beam Reconstruction, MIT Ph.D. Thesis, 2002

Formulae by Yang and Katsevich

Katsevich (2003)

$$f(x) = -\frac{1}{8\pi} \int_{\Lambda} \frac{\sum c_m(\lambda, x)}{|x - \Phi(\lambda)|} \int_{0}^{2\pi} \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda'), \cos \gamma \alpha(\lambda, x) + \frac{\partial}{\partial \lambda'} \int_{0}^{2\pi} \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda'), \cos \gamma \alpha(\lambda, x) + \frac{\partial}{\partial \lambda'} \int_{0}^{2\pi} \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda'), \cos \gamma \alpha(\lambda, x) + \frac{\partial}{\partial \lambda'} \int_{0}^{2\pi} \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda'), \cos \gamma \alpha(\lambda, x) + \frac{\partial}{\partial \lambda'} \int_{0}^{2\pi} \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda'), \cos \gamma \alpha(\lambda, x) + \frac{\partial}{\partial \lambda'} \int_{0}^{2\pi} \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda'), \cos \gamma \alpha(\lambda, x) + \frac{\partial}{\partial \lambda'} \int_{0}^{2\pi} \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda'), \cos \gamma \alpha(\lambda, x) + \frac{\partial}{\partial \lambda'} \int_{0}^{2\pi} \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda'), \cos \gamma \alpha(\lambda, x) + \frac{\partial}{\partial \lambda'} \int_{0}^{2\pi} \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda'), \cos \gamma \alpha(\lambda, x) + \frac{\partial}{\partial \lambda'} \int_{0}^{2\pi} \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda'), \cos \gamma \alpha(\lambda, x) + \frac{\partial}{\partial \lambda'} \int_{0}^{2\pi} \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda'), \cos \gamma \alpha(\lambda, x) + \frac{\partial}{\partial \lambda'} \int_{0}^{2\pi} \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda'), \cos \gamma \alpha(\lambda, x) + \frac{\partial}{\partial \lambda'} \int_{0}^{2\pi} \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda'), \cos \gamma \alpha(\lambda, x) + \frac{\partial}{\partial \lambda'} \int_{0}^{2\pi} \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda'), \cos \gamma \alpha(\lambda, x) + \frac{\partial}{\partial \lambda'} \int_{0}^{2\pi} \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda'), \cos \gamma \alpha(\lambda, x) + \frac{\partial}{\partial \lambda'} \int_{0}^{2\pi} \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda'), \cos \gamma \alpha(\lambda, x) + \frac{\partial}{\partial \lambda'} \int_{0}^{2\pi} \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda'), \cos \gamma \alpha(\lambda, x) + \frac{\partial}{\partial \lambda'} \int_{0}^{2\pi} \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda'), \cos \gamma \alpha(\lambda, x) + \frac{\partial}{\partial \lambda'} Df(\Phi(\lambda, x) + \frac{\partial}{\partial \lambda'} Df(\Phi$$

Forward projection and spherical space

• Forward projection maps \mathbb{E}^3 to \mathbb{P}^2

 $\Phi(\lambda)$: source orbit

Fiber bundle structure

- Attach to each source point a unit sphere which represents a local fiber
- Fiber bundle: the union of all the spheres

Calculations within and across projections

- Within projection: calculations within each fiber require only local coordinates
- Across projections: differentiation along curves on the fiber bundle requires global coordinates

Euclidean moving frames

 At each source point attach an orthonormal Euclidean basis, i.e.,

 $\Phi(\lambda)$

Euclidean moving frames (Cont'd)

- Allows easy exchange between local and global coordinates of points, lines and planes
- Allows treating the non-Euclidean space, "*locally*", as an Euclidean space equipped with Euclidean-like coordinates

Selection of moving frame basis

Many choices in selecting moving frame bases,
i.e.,

• Main considerations:

simplify coordinate computation, ease system alignment

Moving frame basis (I)

• Under cylindrical symmetry:

Good selection of moving frames simplifies the geometric computation as well as system alignment.

Moving frame basis (II)

• Under spherical symmetry:

There is an alignment step in system design to align the axes of the detectors to two of the axes of the moving frames.

Integral within projection

- Integration in the fiber space
- Local coordinate and discretization
- Irregularity in sampling

Exterior differentiation: differentiation across projections

- Two fibers are disjoint excepts at a zero measure set
- Differentiation across fibers can't be replaced by differentiation within the closed fiber

Exterior derivative (Cont'd)

- Parallel lines: having the same α
- The rotational matrix is made up of the three orthonormal basis vectors: $R(\lambda) = (u(\lambda), v(\lambda), w(\lambda))$
- Local→global→local coordinate transforms:

Exterior derivative (Cont'd)

- Parallel planes: having the same β
- Local→global→local coordinate transforms
- Local coordinate of the intersection line (s, ϕ)

$$\begin{cases} s = D \frac{l_2}{\sqrt{R^2 - l_2^2}} \\ \phi = \arctan\left(\frac{\beta \cdot v}{\beta \cdot u}\right) \end{cases}$$

Summary

- New geometric representations
- A new "method of moving frames" applied to conebeam reconstruction (a new computational framework)
- 3D discretization of the curved transform space, applicable to all cone-beam geometries
- Methods to compute the exterior derivatives
- Further study on sampling/interpolation schemes to improve algorithm efficiency
