Scheme

1. Special Forms
   (a) quote - `(quote expr)`
      Returns whatever the reader built for expr.
   (b) ’thing - syntactic sugar for `(quote thing)`.

2. Procedures
   (a) `(eq? v1 v2)` - returns true if v1 and v2 are bitwise identical. “Works on” symbols, booleans, and pairs. Doesn’t “work on” numbers and strings.
   (b) `(eqv? v1 v2)` - like `(eq?)` except it “works on” numbers as well.
   (c) `(equal? v1 v2)` - return true if v1 and v2 print out the same. “Works on” almost everything.

Problems

1. Evaluation - give printed value, assuming x is bound to 5.
   (a) ’3
   (b) ’x
   (c) ’’x
   (d) `(quote (3 4))`
   (e) `’(+ 3 4)`
   (f) `(if ’(= x 0) 7 8)`
   (g) `(eq? ’x ’X)`
   (h) `(eq? (list 1 2) (list 1 2))`
   (i) `(equal? (list 1 2) (list 1 2))`
   (j) `(let ((a (list 1 2))) (eq? a a))`
Boolean Formulas

A boolean formula is a formula containing boolean operations and boolean variables. A boolean variable is either true or false. and, or, and not are all boolean operations. For the purposes of this problem, and and or will be defined to take exactly two inputs.

Example formulas:

\[
\begin{align*}
a \\
(not b) \\
(or b (not c)) \\
(and (not a) (not c)) \\
(not (or (not a) c)) \\
(and (or a (not b)) (or (not a) c))
\end{align*}
\]

Some useful procedures:

\[
\begin{align*}
(define (variable? exp)
  (symbol? exp))
\end{align*}
\]

\[
\begin{align*}
(define (make-variable var)
  var)
\end{align*}
\]

\[
\begin{align*}
(define (variable-name exp)
  exp)
\end{align*}
\]

\[
\begin{align*}
(define (or? exp)
  (and (pair? exp) (eq? (car exp) 'or)))
\end{align*}
\]

\[
\begin{align*}
(define (make-or exp1 exp2)
  (list 'or exp1 exp2))
\end{align*}
\]

\[
\begin{align*}
(define (or-first exp)
  (cadr exp))
\end{align*}
\]

\[
\begin{align*}
(define (or-second exp)
  (caddr exp))
\end{align*}
\]

\[
\begin{align*}
(define (and? exp)
  (and (pair? exp) (eq? (car exp) 'and)))
\end{align*}
\]

\[
\begin{align*}
(define (make-and exp1 exp2)
  (list 'and exp1 exp2))
\end{align*}
\]

\[
\begin{align*}
(define (and-first exp)
  (cadr exp))
\end{align*}
\]

\[
\begin{align*}
(define (and-second exp)
  (caddr exp))
\end{align*}
\]

4. Write selectors, constructor, and predicate for not
5. Given a boolean expression and a set of variable assignments, evaluate the expression to decide whether the result is \texttt{#t} or \texttt{#f}. Assume that you have a procedure \texttt{(variable-value name environment)}, which takes a variable name and list of values and returns the value assigned to the variable, if a binding for it exists, or throws an error if no binding is found.

\begin{verbatim}
(define (eval-boolean exp env)

6. The evaluator as described so far only allows expressions to be either boolean operators or variable values. Extend the operator so that expressions can include literal booleans as well, so that evaluating expressions such as \texttt{(and #t #f)} work.
