# Techniques for Inverted Index Compression 

 Giulio Ermanno Pibiri, Rossano VenturiniPresented by: Giorgi KIdiashvili

## What Is An Inverted Index?

- A data structure used in information retrieval systems to efficiently retrieve documents or web pages containing a specific term or set of terms.
- In an inverted index, the index is organized by terms, and each term points to a list of documents or web pages that contain that term.
- Typically used to optimize efficiency of data retrieval queries.
- Has a good structure for optimizations.
- Used in variety of applications:
- Search engines
- Document retrieval systems
- Recommendation systems
- Social networks
- Bioinformatics

O Database management systems

- etc

## Inverted Index Example

What is the highest rated class about Optimizations?

## Problem: Inverted Index can be very large!

- Google Search index contains hundreds of bill rof over IOO,000,000 gigabytes in size ${ }^{[1]}$.
- The posts index alone in Facebos cam Search ous over 700 TB of data and includes over

## Goals

Survey encoding algorithms suitable for Inverted Index Compression

Characterize their performance through experimentations

Evaluate them using space and memory usage

## Overview

- High level definition of compression techniques split into three subgroups.
- Description of the evaluation methodology.
- Experiment results and final thoughts.

## Inverted Index Compression Technique Types

## Integer Compressors

- Unary and Binary
- Gamma and Delta
- Golomb
- Rice
- Zeta
- Fibonacci
- Variable-Byte
- SC-Dense

## Hist Compressors

- Binary packing
- Simple
- PForDelta
- Elias-Fano
- Interpolative
- Directly-addressable
- Hybrid
- Entropy encodings

Entire Inder Compressors

- Clustered
- ANS-based
- Dictionary-based

## Timeline of Compression Techniques

## Integer Compressors

## Integer Encoding Goals

- Map each integer to unique binary string codeword.
- Ideally $|C(x)| \approx \log _{2}(1 / \mathbb{P}(x))$.
- Good decoding and encoding performance.
- Low overhead for storing the encoding details.

## Prefix-free Code

- No codeword is a prefix of another codeword.
- Can be rearranged so that lexicographical ordering stays intact.
- In this lexicographical ordering, codewords with same lengths will end up in consecutive order.
- Can be uniquely decoded.
- Lexicographical ordering can be exploited to increasing encoding and decoding performance.

## Prefix-free Encodings

| $(\mathrm{a})$ |  |  |  |
| :--- | :--- | :---: | :---: |
| $x$ | Codewords | Lengths | Values |
| 1 | 0 | 1 | 0 |
| 2 | 100 | 3 | 64 |
| 3 | 101 | 3 | 80 |
| 4 | 11000 | 5 | 96 |
| 5 | 11001 | 5 | 100 |
| 6 | 11010 | 5 | 104 |
| 7 | 11011 | 5 | 108 |
| 8 | 1110000 | 7 | 112 |
| - | - | - | 127 |

(b)

| Lengths | First | Values |
| :---: | :--- | :---: |
| 1 | 1 | 0 |
| 2 | 2 | 64 |
| 3 | 2 | 64 |
| 4 | 4 | 96 |
| 5 | 4 | 96 |
| 6 | 8 | 112 |
| 7 | 8 | 112 |
| - | 9 | 127 |

## Prefix-free Encodings

## Encode( $x$ ) :

determine $\ell$ such that $\operatorname{first}[\ell] \leq x<\operatorname{first}[\ell+1]$
offset $=x-$ first $[\ell]$
jump $=1 \ll(M-\ell)$
Write $(($ values $[\ell]+$ offset $\times$ jump $) \gg(M-\ell), \ell)$
Decode() :
determine $\ell$ such that values $[\ell] \leq$ buffer $<$ values $[\ell+1]$ offset $=($ buffer - values $[\ell]) \gg(M-\ell)$ buffer $=(($ buffer $\ll \ell) \&$ MASK $)+$ Take $(\ell)$ return first $[\ell]+$ offset

## Integer Encoding

| Encoding | Optimal when $\mathbb{P}(\boldsymbol{x}) \approx$ |
| :--- | :---: |
| Unary | $1 / 2^{x}$ |
| Binary | $1 / 2^{k}$ |
| Gamma | $1 /\left(2 x^{2}\right)$ |
| Delta | $1 /\left(2 x\left(\log _{2} x\right)^{2}\right)$ |
| Golumb | $p(1-p)^{x-1}$ |
| Rice | $p(1-p)^{x-1}$ |
| Zeta | $1 /\left(\zeta(\alpha) x^{\alpha}\right)$ |
| Fibonnaci | $1 /\left(2 x^{\frac{1}{\log _{2} \phi}}\right) \approx 1 /\left(2 x^{1.44}\right)$ |
| VByte | $\sqrt[7]{1 / x^{8}}$ |
| SC-Dense | $(s+c)^{-k(x)}$ |

## Codeword Length

## Integer Encoding

| Encoding | Optimal when $\mathbb{P}(\boldsymbol{x}) \approx$ |
| :--- | :---: |
| Unary | $1 / 2^{x}$ |
| Binary | $1 / 2^{k}$ |
| Gamma | $1 /\left(2 x^{2}\right)$ |
| Delta | $1 /\left(2 x\left(\log _{2} x\right)^{2}\right)$ |
| Golumb | $p(1-p)^{x-1}$ |
| Rice | $p(1-p)^{x-1}$ |
| Zeta | $1 /\left(\zeta(\alpha) x^{\alpha}\right)$ |
| Fibonnaci | $1 /\left(2 x^{\frac{1}{\log _{2} \phi}}\right) \approx 1 /\left(2 x^{1.44}\right)$ |
| VByte | $\sqrt[7]{1 / x^{8}}$ |
| SC-Dense | $(s+c)^{-k(x)}$ |

## Unary Encoding

- Encode $x$ as $1^{x-1} 0$.
- $|C(x)|=x$.
- Optimal when $\mathbb{P}(x) \approx 1 / 2^{x}$.

| $x$ | $\mathrm{U}(x)$ |
| :--- | :--- |
| 1 | 0 |
| 2 | 10 |
| 3 | 110 |
| 4 | 1110 |
| 5 | 11110 |
| 6 | 111110 |
| 7 | 111110 |
| 8 | 1111110 |
|  |  |
|  |  |
|  |  |

## Binary Encoding

- Encode $x$ as $\operatorname{bin}(x-1)$.
- $|C(x)| \approx \log _{2}(\max \{x\})=k$.
- Optimal when $\mathbb{P}(x) \approx 1 / 2^{k}$.

| $x$ |  | $\mathrm{~B}(x)$ |
| :--- | :--- | :--- |
| 1 | 0 |  |
| 2 | 1 |  |
| 3 | 10 |  |
| 4 | 11 |  |
| 5 | 100 |  |
| 6 | 101 |  |
| 7 | 110 |  |
| 8 | 111 |  |
|  |  |  |
|  |  |  |
|  |  |  |
|  |  |  |
|  |  |  |

## Gamma Encoding

- Encode $x$ as unary representation of $|\operatorname{bin}(x)|$ followed by $(|\operatorname{bin}(x)|-1)$ bits from $\operatorname{bin}(x)$.
- $|C(x)|=2|\operatorname{bin}(x)|-1$.
- Optimal when $\mathbb{P}(x) \approx 1 /\left(2 x^{2}\right)$.

| $x$ | $\gamma(x)$ |
| :--- | :--- |
| 1 | 0. |
| 2 | 10.0 |
| 3 | 10.1 |
| 4 | 110.00 |
| 5 | 110.01 |
| 6 | 110.10 |
| 7 | 110.11 |
| 8 | 1110.000 |
|  |  |
|  |  |
|  |  |

## Delta Encoding

- Gamma encoding of the length of the binary representation followed by $(|\operatorname{bin}(x)|-1)$ bits from $\operatorname{bin}(x)$.
- Replace first part in Gamma by $\gamma(|\operatorname{bin}(x)|)$.
- $|C(x)|=|\gamma(|\operatorname{bin}(x)|)|+|\operatorname{bin}(x)|-1$.
- Optimal when $\mathbb{P}(x) \approx 1 /\left(2 x\left(\log _{2} x\right)^{2}\right)$.

| $x$ | $\boldsymbol{\delta}(x)$ |
| :--- | :--- |
| 1 | 0. |
| 2 | 100.0 |
| 3 | 100.1 |
| 4 | 101.00 |
| 5 | 101.01 |
| 6 | 101.10 |
| 7 | 101.11 |
| 8 | 11000.000 |
|  |  |
|  |  |

## Integer Encoding

| Encoding | Optimal when $\mathbb{P}(\boldsymbol{x}) \approx$ |
| :--- | :---: |
| Unary | $1 / 2^{x}$ |
| Binary | $1 / 2^{k}$ |
| Gamma | $1 /\left(2 x^{2}\right)$ |
| Delta | $1 /\left(2 \boldsymbol{x}\left(\log _{2} \boldsymbol{x}\right)^{\mathbf{2}}\right)$ |
| Golumb | $p(1-p)^{x-1}$ |
| Rice | $\boldsymbol{p}(1-\boldsymbol{p})^{x-1}$ |
| Zeta | $1 /\left(\zeta(\alpha) x^{\alpha}\right)$ |
| Fibonnaci | $1 /\left(2 x^{\frac{1}{\log _{2} \phi}}\right) \approx 1 /\left(2 x^{1.44}\right)$ |
| VByte | $\sqrt[7]{1 / x^{8}}$ |
| SC-Dense | $(s+c)^{-k(x)}$ |

## Golomb Encoding

- Unary encoding of quotient $(q)$ followed by binary codeword for remainder $(r)$ with parameter $b>1$.
- Optimal when $\mathbb{P}(x)=p(1-p)^{x-1}$ (geometric).

| $x$ | $G_{2}(x)$ |
| :--- | :--- |
| 1 | 0.0 |
| 2 | 0.1 |
| 3 | 10.0 |
| 4 | 10.1 |
| 5 | 110.0 |
| 6 | 110.1 |
| 7 | 1110.0 |
| 8 | 1110.1 |
|  |  |
|  |  |
|  |  |
|  |  |

## Rice Encoding

- Special case of Golumb when $b=2^{k}$.
- $\mid$ Rice $_{k}(x) \mid=(x-1) / 2^{k}+k+1$.

| $x$ | $G_{2}(x)$ |
| :--- | :--- |
| 1 | 0.0 |
| 2 | 0.1 |
| 3 | 10.0 |
| 4 | 10.1 |
| 5 | 110.0 |
| 6 | 110.1 |
| 7 | 1110.0 |
| 8 | 1110.1 |
|  |  |
|  |  |
|  |  |
|  |  |

## Integer Encoding

| Encoding | Optimal when $\mathbb{P}(\boldsymbol{x}) \approx$ |
| :--- | :---: |
| Unary | $1 / 2^{x}$ |
| Binary | $1 / 2^{k}$ |
| Gamma | $1 /\left(2 x^{2}\right)$ |
| Delta | $1 /\left(2 x\left(\log _{2} x\right)^{2}\right)$ |
| Golumb | $p(1-p)^{x-1}$ |
| Rice | $\boldsymbol{p ( 1 - p ) ^ { x - 1 }}$ |
| Zeta | $1 /\left(\zeta(\alpha) x^{\alpha}\right)$ |
| Fibonnaci | $1 /\left(2 x^{\left.\frac{1}{\log _{2} \phi}\right)}\right) \approx 1 /\left(2 x^{1.44}\right)$ |
| VByte | $\sqrt[7]{1 / x^{8}}$ |
| SC-Dense | $(s+c)^{-k(x)}$ |

## Byte-aligned Encoding(VByte)

- Idea: align the bits used in codeword to byte or word lengths for faster reads.
- Most significant bit in each byte is reserved as a continuation bit, others used for data.
- Exploits SIMD instruction parallelisms and other hardware optimizations.
- OPT-Vbyte is a variation where continuation bits are stored separately.
- Optimal when $\mathbb{P}(x) \approx \sqrt[3]{1 / x^{4}}$ or $\mathbb{P}(x) \approx \sqrt[7]{1 / x^{8}}$.

## List Compressors

## List Compressors

- *Assume that integers are strongly ordered per list.
- Idea: encode entire list instead of each single integer separately.
- Theoretical lower bound on needed bits for encoding $n$ integers from $U$ :

$$
\left\lceil\left.\log _{2}\binom{U}{n} \right\rvert\,=n\left\lceil\log _{2}(e U / n)\right\rceil-\Theta\left(n^{2} / U\right)-0(\log n) \approx n\left\lceil\log _{2}(U / n)\right\rceil+1.443 n\right.
$$

- Can be approximated considering that lists feature cluster of close integers.
- Given the existence of these clusters can encode relative changes.
- Might help if we reorder docIDs to form larger clusters.

## Binary Packing

- Partition sequence into blocks and encode them separately.
- Gaps between the integers can also be used.
- Size of blocks can be fixed but better to be of variable size.
- Descriptor is needed for each variable sized block.
- Blocks can further be hardware-aligned (SIMD-BP128).

## Simple Encoders

Table 6. Nine Different Ways of Packing Integers in a 28 -Bit Segment as Used by Simple9

- Idea: partition on fixed-memory units and pack as many integers in them as possible.
- Good compression and high decompression rates.
- Simple16 has 16 possible configurations and uses 32-bit words.
- QMX packs into 128 or 256 -bit words

| 4-Bit Selector | Integers | Bits per Integer | Wasted Bits |
| :---: | :---: | :---: | :---: |
| 0000 | 28 | 1 | 0 |
| 0001 | 14 | 2 | 0 |
| 0010 | 9 | 3 | 1 |
| 0011 | 7 | 4 | 0 |
| 0100 | 5 | 5 | 3 |
| 0101 | 4 | 7 | 0 |
| 0110 | 3 | 9 | 1 |
| 0111 | 2 | 14 | 0 |
| 1000 | 1 | 28 | 0 | and stores the selectors separately.

## PForDelta(PFor) Encoders

Problem with Simple: space-inefficient when a block contains just one large value.

- Solution: pick a range $\left[b, b+2^{k}-1\right]$ that fits majority of the integers.
- Encode them with k bits.
- Mark other integers as exceptions and encode them separately with a different encoder algorithm.

$$
[3,4,7,21,9,12,5,17,6,2,34]
$$

$\left[3,4,7,{ }^{*}, 9,12,5,{ }^{*}, 6,2,{ }^{*}\right]-[21,17,34]$

## Elias-Fano Encoding

- Given $n$ sorted integers from range [1.. U] - Universe.
- Split integers into $l=\left\lceil\log _{2}(U / n)\right\rceil$ low bits and $\left\lceil\log _{2} U\right\rceil-l \approx\left\lfloor\log _{2} n\right\rfloor$ high bits.
- Encode low bits separately with $n\left\lceil\log _{2}(U / n)\right\rceil$ size bitvector.
- Encode high bits separately with $2 n$ bits:
- Observe that $0 \leq h_{i} \leq n$. And that $h_{i-1} \leq h_{i}$.
- For each element, set $\left(h_{i}+i\right)$ th bit to 1 .

Theoretical lig:
$n\left\lceil\log _{2}(\mathbb{U} / n)\right\rceil+1.443 n$

- As a result we will get unary encodings of how many integers have $h_{i}$ equal to particular value.

## $E F(S(n, U)) \leq n\left[\log _{2}(U / n)\right]+2 n$

## Elias-Fano Encoding

Table 7. Example of Elias-Fano Encoding Applied to the Sequence

$$
\mathcal{S}=[3,4,7,13,14,15,21,25,36,38,54,62]
$$

| $\mathcal{S}$ | 3 | 4 | 7 | 13 | 14 | 15 | 21 | 25 | 36 | 38 |  | 54 | 62 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| high | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 1 |
|  | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | 1 | 1 |
|  | 0 | 0 | 0 | 1 | 1 | 1 | 0 | 1 | 0 | 0 | 1 | 0 | 1 |
| low | 0 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 1 | 1 |  | 1 | 1 |
|  | 1 | 0 | 1 | 0 | 1 | 1 | 0 | 0 | 0 | 1 |  | 1 | 1 |
|  | 1 | 0 | 1 | 1 | 0 | 1 | 1 | 1 | 0 | 0 |  | 0 | 0 |
| $H$ | 1110 |  |  |  |  |  |  |  |  |  |  | 1110 | 10 |
| $L$ | 011.100 .111 | 101.110 .111 | 101 | 001 | 100.110 |  | 110 | 110 |  |  |  |  |  |

## Elias-Fano Encoding: Random Access

## Problem: how to decode a single individual integer?

- Get $l_{i}$ low bits with direct access.
- Implement data structure to get $\operatorname{Select}_{b}(i)=($ ith bit set to b in H) in O(1).
- Then $h_{i}=\operatorname{Select}_{1}(i)-i$.
- Concatenate $l_{i}$ and $h_{i}$ to get $S_{i}$.
- Runs in O(1).

## Elias-Fano Encoding: Successor Oueries

Problem: how to get smallest $y \geq x$ for some $x$ ?

- Let $h_{x}$ be the high bits of $x$.
- Set $i=$ Select $_{o}\left(h_{x}\right)-h_{x}+1$ and $\mathrm{j}=$ Select $_{o}\left(h_{x}+1\right)-h_{x}$.
- [i..j] interval is where $y$ must be.
- Do binary search.
- Runs in $\mathrm{O}(1+\log (U / n))$.

## Elias-Fano Encoding: Partitioning by Cardinality(PEF)

## Observation: in the inverted index integers are clustered.

- Partition into $k$ blocks of variable length
- On the first level encode with EF (1) $\left\{U_{1}, \ldots, U_{k}\right\}$ upper bounds of the blocks and (2)prefix-summed sequence of sizes of blocks.
- On the second level encode the blocks themselves.
- Suppose a block with size $b$ and universe $M$ :

1. If $b=M$ - each element appears exactly once nothing to encode on the $2^{\text {nd }}$ level.
2. If $b>M / 4-$ since $E F(b, M)>M$ use characteristic encoding of size $M$.
3. If $b \leq M / 4$ - use EF on the 2nd level.

- It can be shown that using DP to determine blocks sizes is only $(1+\epsilon)$ away from the optimal. But gets worse if $\epsilon$ is fixed.

## Elias-Fano Encoding: Partitioning by Universe

## Observation: high and low bit split can be chosen arbitrarily.

- Roaring: partition $U\left(2^{32}\right)$ into chunk spanning $2^{16}$ values each:

1. If a chunk is sparse (less than $2^{12}$ elements), encode as a sorted array of 16 -bit integers.
2. If a chunk is dense (more than $2^{12}$ elements), encode as a bitmap.
3. If a chunk is full ( $2^{16}$ elements), encode implicitly.

- Slicing: similar to Roaring but continue encoding recursively if the chunk is sparse.

## Binary Interpolative Code (BIC)

## *Remember: strongly sorted sequence of clustered integers.

- Idea: fully use the clustering prior of the integers in the index, by squashing together any runs of consecutive integers.
- Recursively divide the index and the value range in half while encoding the middle element with as little amount of bits as possible
- In particular in a given interval $S[i . . j]$ with $l \leq S[i]$ and $S[j] \leq h$ :

1. Encode $S[(i+j) / 2]-l-m+1$ using $\left\lceil\log _{2}(h-l-j+i)\right\rceil$ bits.
2. Continue encoding of $S[i . .(i+j) / 2-1]$ and $S[(i+j) / 2+1 . . j]$ recursively.
3. If $l+j-i=h$ holds, stop recursion and encode implicitly.

## Binary Interpolative Code (BIC)

## Entropy Encodings

## Usually Good average codeword length, but can not compete with other methods.

- Huffman: Maintain a candidate set of tree and each step merge trees with lowest weight. Assign codewords based on the symbol's location in the eventual tree. Let $L$ be average Huffman codeword length:

○ $L$ is minimum possible among all the prefix-free encodings.
○ $H_{0} \leq L<H_{0}+1$ where $H_{0}$ bits is the entropy of the system.

- Arithmetic: partition [0,1) interval to proportional length of system probabilities, pick first interval and recursively partition it. Eventually emit real number $x$ from $\left[l_{n}, r_{n}\right)$.
- Requires infinite precision arithmetic but can be approximated.
- Takes at most $n H_{0}+2$ bits to encode entire sequence. In practice $n H_{0}+2 n / 100$ bits.
- Asymmetric Numeral Systems(ANS): Generate a frame from the sequence symbols with retaining the same probabilities. To encode start from column 0 and move to the column corresponding to the first symbol in the sequence. Continue the process emitting column number along the way.

## Full Index Compressors

## Clustered

- Group clusters of the lists sharing many integers.
- All lists in the cluster are then encoded with respect to the reference list.
- Used PEF for such encoding.

## ANS based

- Universe can be very large even if only gaps are taken into account.
- Pre-process input list to a sequence of bytes.
- Then apply a combination of VByte and ANS.

Dictionary based(DINT)

- Store most frequent $2^{b}$ patterns in dictionary for some $b$
- Use this dictionary to encode subsequences of gaps.
- Can be further optimized if we take advantage of the presence of runs of 1 s in codeword modelling.

## Dictionary-based Coding

Fig. 6. A dictionary-based encoded stream example, where dictionary entries corresponding to $\{1,2,4,8,16\}$ long integer patterns, runs, and exceptions are labeled with different shades. Once provision has been made for such a dictionary structure, a sequence of gaps can be modeled as a sequence of codewords $\left\{c_{k}\right\}$, each being a reference to a dictionary entry, as represented with the encoded stream in the picture. Note that, for example, codeword $c_{9}$ signals an exception, and therefore the next symbol $e$ is decoded using an escape mechanism.

## Experimentations

## Experimental Setting

- Machine: Intel i9-9900K(@3.6Ghz), 64GB DDR3 RAM, Running Linux 5 (64bit)
- Code written in C++ with the highest optimization enabled:
- Flags -03 and -march=native
- Datasets:
(a) Basic Statistics

|  | Gov2 | ClueWeb09 | CCNews |
| :--- | ---: | ---: | ---: |
| Lists | 39,177 | 96,722 | 76,474 |
| Universe | $24,622,347$ | $50,131,015$ | $43,530,315$ |
| Integers | $5,322,883,266$ | $14,858,833,259$ | $19,691,599,096$ |
| Entropy of the gaps | 3.02 | 4.46 | 5.44 |
| $\left\lceil\log _{2}\right\rceil$ of the gaps | 1.35 | 2.28 | 2.99 |

(b) TREC 2005/06 Queries

|  | Gov2 |  |  | ClueWeb09 |

## Experimental Methodology

- Data structure is a memory mapped from the file.
- Warm-up run is executed before the experiments are run.
- Testing on sequential reads.
- Queries consist of randomly chosen 1000 samples of intersection(AND) and union(OR) queries consisting of terms from 2 to $5+$.
- Average run time reported among 3 runs of the same experiment.
- What to watch out for:
- Space Usage: measured in number of bits per integer bits/int.
- Access Time: sequential or random. Measured in ns/int.

## Tested Algorithms

Table 9. Different Tested Index Representations

|  | Method | Partitioned by | SIMD | Alignment | Description |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Variable Byte | VByte | Cardinality | Yes | Byte | Fixed-size partitions of 128 |
| timized VByte | Opt-VByte | Cardinality | Yes | Bit | Variable-size partitions |
| Interpolative | BIC | Cardinality | No | Bit | Fixed-size partitions of 128 |
| Delta | $\delta$ | Cardinality | No | Bit | Fixed-size partitions of 128 |
| Rice | Rice | Cardinality | No | Bit | Fixed-size partitions of 128 |
| Elias-Fano | PEF | Cardinality | No | Bit | Variable-size partitions |

## Space/Time Trade-Offs

Fig. 7. Space/time trade-off curves for the ClueWeb09 dataset.

## Final Thoughts

- If you want:
- Speed: Roaring.
- Compression effectiveness: BIC.
- Best of both Worlds: PEF, DINT or Slicing.
- Try to utilize SIMD and aligning if possible to get better performance!
- How Zeta or Fibonacci would perform on Inverted Index?

## Acknowledgments

- Giulio Ermano Pibiri and Rossano Venturini.
- Professors Charles and Julian.
- All the authors of various algorithms described above.

## Thank you

## Appendix

## Exponential Golomb Encoding

- Define $B=\left[0,2^{k}, \sum_{i=0}^{1} 2^{k+i}, \sum_{i=0}^{2} 2^{k+i}, \ldots\right]$.
- Unary encoding of bucket identifier followed by binary encoding of bucket specific offset.
- $|C(x)|=2 h+1$ where $B[h]<x \leq B[h+1]$.

| $x$ | $\operatorname{Exp}_{2}(x)$ |
| :--- | :--- |
| 1 | 0.00 |
| 2 | 0.01 |
| 3 | 0.10 |
| 4 | 0.11 |
| 5 | 10.000 |

| 7 | 10.010 |
| 8 | 10.011 |
|  |  |
|  |  |
|  |  |
|  |  |

## Zeta Encoding

- Exponential Golumb with buckets: $\left[0,2^{k}-1,2^{2 k}-1,2^{3 k}-1 \ldots\right]$.
- Unary encoding of bucket identifier followed by a minimal binary codeword for bucket specific offset.
- $Z_{1}$ coincides with $\operatorname{Exp} G_{0}$ and Gamma.
- Optimal when $\mathbb{P}(x)=1 /\left(\zeta(\alpha) x^{\alpha}\right)$ distributed according to a power law and $\zeta()$ is Riemann zeta function.

| $x$ | $Z_{2}(x)$ |
| :--- | :--- |
| 1 | 0.0 |
| 2 | 0.10 |
| 3 | 0.11 |
| 4 | 10.000 |

| 8 | 0 | 0 | 0 | 0 | 1 |
| $F_{i}$ | 1 | 2 | 3 | 5 | 8 |

(b) Lexicographic Codewords
$\left.\begin{array}{llllll}\hline x & \mathrm{~F}(x) & & & \\ \hline 1 & 0 & 0 & & & \\ 2 & 0 & 1 & 0 & & \\ 3 & 0 & 1 & 1 & 0 & \\ 4 & 0 & 1 & 1 & 1 & \\ 5 & 1 & 0 & 0 & 0 & 0 \\ 6 & 1 & 0 & 0 & 0 & 1 \\ 7 & 1 & 0 & 0 & 1 & 0 \\ 8 & 1 & 0 & 0 & 1 & 1\end{array}\right)$ $/\left(2 x^{1.44}\right)$

## SC-Dense Encoding

- Have $c$ continuers and $s$ stoppers, where $c+s=2^{8}$
- Can be better adapt for the distribution of the words
- $|C(x)|=k(x)\left[\log _{2}(s+c)\right]$ where $k(x)$ is number of words needed

| $x$ | $\mathrm{SC}(4,4, x)$ | $\mathrm{SC}(5,3, x)$ |

| 9 | 101.000 | 101.011 |
| 10 | 101.001 | 101.100 |

| $x$ | $\mathrm{SC}(4,4, x)$ | $\mathrm{SC}(5,3, x)$ |
| :---: | :---: | :---: |
| 11 | 101.010 | 110.000 |
| 12 | 101.011 | 110.001 |
| 13 | 110.000 | 110.010 |
| 14 | 110.001 | 110.011 |
| 15 | 110.010 | 110.100 |
| 16 | 110.011 | 111.000 |
| 17 | 111.000 | 111.001 |
| 18 | 111.001 | 111.010 |
| 19 | 111.010 | 111.011 |
| 20 | 111.011 | 111.100 |

- Optimal when $\mathbb{P}(x) \approx(s+c)^{-k(x)}$

## Huffman Coding

| symbols | weights | lengths | codewords |
| :---: | :---: | :---: | :--- |
| 2 | 8 | 2 | 00 |
| 5 | 7 | 2 | 01 |
| 6 | 2 | 3 | 100 |
| 7 | 2 | 3 | 101 |
| 1 | 2 | 4 | 1100 |
| 3 | 2 | 4 | 1101 |
| 4 | 1 | 4 | 1110 |
| 8 | 1 | 4 | 1111 |

Fig. 5. An example of Huffman coding applied to a sequence of size 25 with symbols $1 . .8$ and associated weights $[2,8,2,1,7,2,2,1]$.

## Arithmetic Numeral Systems(ANS)

- Generate a frame from the sequence symbols with retaining the same probabilities
- To encode start from column 0 and move to the column corresponding to the first symbol in the sequence. Continue the process emitting column number along the way.
(a)

| $\Sigma$ | $\mathbb{P}$ | Codes |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $a$ | $1 / 2$ | 1 | 2 | 3 | 7 | 8 | 9 | 13 | 14 | 15 | 19 |
| $b$ | $1 / 3$ | 4 | 5 | 10 | 11 | 16 | 17 | 22 | 23 | 28 | 29 |
| $c$ | $1 / 6$ | 6 | 12 | 18 | 24 | 30 | 36 | 42 | 48 | 54 | 60 |
|  |  | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |

(b)

| $\Sigma$ | $\mathbb{P}$ | Codes |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $a$ | $1 / 2$ | 2 | 4 | 6 | 8 | 10 | 12 | 14 | 16 | 18 | 20 |
| $b$ | $1 / 4$ | 3 | 7 | 11 | 15 | 19 | 23 | 27 | 31 | 35 | 39 |
| $c$ | $1 / 4$ | 1 | 5 | 9 | 13 | 17 | 21 | 25 | 29 | 33 | 37 |
|  |  | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
