< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

## Motivation

Many interesting dynamical systems have natural **multiscale structure**, in time and/or in space.

► Goal: *Statistical model reduction* that systematically takes advantage of this structure whenever possible.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

Advantage: Higher-accuracy at lower complexity:

- Simpler controllers
- Faster simulations
- Revealing analyses/interpretations

## Approach

A system will be approximated by a collection of *local*, *low-dimensional* systems at different scales:

A globally defined, reduced-order system is obtained by blending or switching between local sub-systems.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

## Approach

- ► Step (1). Analyze the geometry of empirical trajectories ⇒ build multiscale data tree.
  - Nodes are subsets of samples.
- Step (2). Estimate approximating subspaces at nodes of the tree (multiscale data-dependent dictionary), and project.

- POD + Galerkin projection
- Balanced truncation + Petrov-Galerkin projection
- **Step (3)**. Combine subsystems.

## Geometric Data Tree Construction

Given a precision  $\epsilon > 0$ , build a multiscale tree  $\mathcal{T} = \{C_{j,k}\}$ organizing a dataset of N samples  $\{x_i\}_{i=1}^N$  into a spatially hierarchical structure (with e.g., recursive spectral partitioning, METIS, iterated k-means,...).

- Each node corresponds to a subset of the samples (snapshots), C<sub>j,k</sub> (scale j, cell k).
- Children partition the samples of their parent.
- ► Bottom-up pruning: If parent can be encoded to precision e with d ≤ d<sub>max</sub> PCA components, then delete children.

Collection of leaf nodes of  $\mathcal{T}$  is interpreted as a partitioning of the statespace into clusters occurring at different scales.

## Local Reduction: POD

Suppose we are given a tree  $\ensuremath{\mathcal{T}}$  of snapshots for the high-dimensional system

$$\begin{cases} \dot{\mathbf{X}} = f(\mathbf{X}, \mathbf{u}) \\ \mathbf{y} = h(\mathbf{X}) \end{cases}$$

with state  $\mathbf{X} \in \mathbb{R}^D$ , input  $\mathbf{u} \in \mathbb{R}^p$ , and output  $\mathbf{y} \in \mathbb{R}^q$ . For each leaf-node cell  $C_{j,k}, (j,k) \in \text{Leaf}$ , define the local mean

$$c_{j,k} = |\mathsf{C}_{j,k}|^{-1} \sum_{x \in \mathsf{C}_{j,k}} x$$

and covariance

$$\operatorname{cov}_{j,k} = |\mathsf{C}_{j,k}|^{-1} \sum_{x \in \mathsf{C}_{j,k}} (x - c_{j,k}) (x - c_{j,k})^*.$$

# Local Reduction: POD

Take the SVD

$$\operatorname{cov}_{j,k} = U_{j,k} \Sigma_{j,k}^2 U_{j,k}^*.$$

▶ Define P<sub>j,k</sub>: matrix whose rows are the columns of U<sub>j,k</sub> corresponding to the r < D largest singular values.</p>

Local, affine Galerkin projection:

- Consider the dynamics of  $\mathbf{X}' = \mathbf{X} c_{j,k}$
- Project down to the subspace spanned by the r orthonormal rows of P<sub>j,k</sub>.

A reduced-order dynamical system valid in the vicinity of  $c_{j,k}$  is given by

$$\dot{\mathbf{x}}_{j,k} = P_{j,k} f\left(P_{j,k}^* \mathbf{x}_{j,k} + c_{j,k}\right)$$
$$\mathbf{y} = h\left(P_{j,k}^* \mathbf{x}_{j,k} + c_{j,k}\right)$$

for each  $(j,k) \in \text{Leaf}$ .

## Local Reduction: POD - Comments

- Approximation of the statespace with an arrangement of low-dimensional planes.
- Approximating subspaces/dynamics only need to be good locally.
- ► Local systems need not have the same dimension (chosen adaptively based on *ϵ*).
- Approximation captures local input-to-state behavior, but ignores state-to-output properties.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

Approach is similar to (Lall, Marsden, Glavaski '02), but adapted to the localized setting with some modifications.

#### Local Empirical Balanced Truncation

- Controllability tree + local POD.
- Observability tree + local observability subspace estimation.

Local truncation & projection.

#### Controllability tree construction & local POD:

► Simulate the system with  $\mathbf{u}(t) = \mathbf{e}_i \delta(t)$  for i = 1, ..., p and  $\mathbf{X}(0) = 0$ , collect  $N_c$  state trajectory samples.

- Build a controllability tree  $T_c$  to precision  $\epsilon$ .
- ► For each leaf node in the tree, compute the projections (partial isometries) P<sub>j,k</sub> described before.

#### Local observability assessment:

Let  $\{\phi_{j,k}^{(i)}\}_{i=1}^r$  denote the top r orthonormal basis vectors spanning the POD subspace associated to node (j,k) of  $\mathcal{T}_c$ .

▶ For each  $(j,k) \in \text{Leaf}(\mathcal{T}_c)$ , run r simulations of the original system from initial conditions  $\mathbf{X}(0) = \phi_{j,k}^{(i)} + c_{j,k}$ ,  $i = 1, \ldots, r$ , respectively, with  $\mathbf{u}(t) = 0$ . Collect  $N_o$  snapshots each.

- ► Assumes that if dim r POD reduction locally well-approximates the dynamics, then output trajectories should approximately lie in a subspace of dimension ≤ r.
- Total of  $r \cdot |\text{Leaf}|$  short simulations.

Collect the snapshot vectors  $v(\alpha, \beta) = (\mathbf{y}_{\alpha}^{(i)}(t_{\beta}))_{i=1}^r \in \mathbb{R}^r$  into a  $(r \times N_o q)$  matrix  $Y_{j,k}$ .

A rank-r approximation of the true *local* observability gramian  $W_{i,k}^{o}$  is given by

$$W_{j,k}^{o} \approx (P_{j,k}^{*}Y_{j,k})(P_{j,k}^{*}Y_{j,k})^{*} = P_{j,k}^{*}\widetilde{W}_{j,k}^{o}P_{j,k}$$

 $W_{j,k}^o = Y_{j,k}Y_{j,k}^*$  is the  $(r \times r)$  reduced observability gramian local to leaf node (j,k) of  $\mathcal{T}_c$ .

*Note:* We do not explicitly form the large  $(D \times D)$  matrix  $W_{i,k}^o$ .

#### Compute local balancing transformations $T_{j,k}$ :

Define the  $(N_oq \times N_cp)$  Hankel matrix of inner-products local to node (j,k),

$$H_{j,k} = Y_{j,k}^* P_{j,k} X_{j,k}$$

where

•  $Y_{j,k}$  is the  $(r \times N_o q)$  matrix of observability snapshots •  $X_{j,k}$  is the  $(d \times N_c p)$  matrix of controllability snapshots Compute the (sorted, economy) SVD  $H_{j,k} = U_{j,k} \Sigma_{j,k} V_{j,k}^*$ . Truncated balancing coordinate transformation:

$$T_{j,k}^* = P_{j,k}^* Y_{j,k} \tilde{U}_{j,k} \tilde{\Sigma}_{j,k}^{-1/2}, \qquad T_{j,k}^{-1} = X_{j,k} \tilde{V}_{j,k} \tilde{\Sigma}_{j,k}^{-1/2}.$$

where  $\tilde{U}_{j,k}, \tilde{V}_{j,k}, \tilde{\Sigma}_{j,k}$  denote the *d*-truncated submatrices.

#### Local Petrov-Galerkin Projection at node (j, k):

A balanced, reduced order system valid in a local region of the statespace near  $c_{j,k}$  is obtained by performing a Petrov-Galerkin projection onto the *d* directions corresponding to the largest singular values of  $H_{j,k}$ :

$$egin{aligned} & \left( \mathbf{\dot{x}}_{j,k} = T_{j,k} fig(T_{j,k}^{-1} \mathbf{x}_{j,k} + c_{j,k}ig) \ & \mathbf{y} = hig(T_{j,k}^{-1} \mathbf{x}_{j,k} + c_{j,k}ig) \end{aligned}$$

for each  $(j,k) \in \text{Leaf}$ .

Note: *Time* enters via the locality of the transformations.

# Combining Subsystems: Switching

#### Definition

The statespace **regions of responsibility** are defined as the Voronoi regions of the statespace induced by the centers  $\{c_{j,k}\}_{(j,k)\in Leaf}$  under the metric  $\rho$ . In other words, a particular local system with index (j',k') is responsible for a state  $s \in \mathbb{R}^D$  if s is  $\rho$ -closer to  $c_{j',k'}$  than any other leaf node center.

#### Motivates the simple switching rule:

The active system at time  $t_+$  is the system associated to the plane with center  $c_{i,k}$  closest to  $\mathbf{X}(t_-)$ .

## Combining Subsystems: Switching

Hand-off from one system to another is via initial conditions:

Parameterize subsystems with tuples  $\{(\Phi_i,\Psi_i,c_i,f)\}_{i=1}^{|\mathsf{Leaf}|}$  and define

$$f_i(x) \triangleq \Phi_i f(\Psi_i^* x + c_i) \qquad h_i(x) \triangleq h(\Psi_i^* x + c_i)$$

with  $f_i : \mathbb{R}^{d_i} \to \mathbb{R}^{d_i}, d_i = \dim(\operatorname{range} \Phi_i)$ ,

Suppose we switch from system  $i_0$  to  $i_1$  at time  $t_{i_0,i_1}$ .

The global reduced system for  $t_0 \leq t \leq t_{i_1,i_2}$  may be defined as

$$\dot{\mathbf{x}}(t) = \begin{cases} f_{i_0}(\mathbf{x}), \ \mathbf{x}(t_0) = \Phi_{i_0}(\mathbf{X}(t_0) - c_{i_0}), \\ & \text{for } t_0 < t \le t_{i_0, i_1} \\ f_{i_1}(\mathbf{x}), \ \mathbf{x}(t_{i_0, i_1}) \leftarrow \Phi_{i_1}\big(\Psi_{i_0}^* \mathbf{x}(t_{i_0, i_1}) + c_{i_0} - c_{i_1}\big), \\ & \text{for } t_{i_0, i_1} < t \le t_{i_1, i_2}. \end{cases}$$

# Combining Subsystems: Blending

Transitions can be smoothed by blending systems in a neighborhood of a boundary. However,

- Local systems are expressed in different coordinate systems.
- Dimension of local systems can be different.

Solution:

Interpolate in a common space just large enough to include the planes participating in the blend. Common space is found with an SVD.

## Combining Subsystems: Blending

Example: Blending two systems.

- $S \subseteq \mathbb{R}^D$ : high dimensional statespace
- S<sub>i</sub> ⊇ rangeΦ<sub>i</sub>: d<sub>i</sub> dimensional subspace associated to local system i.
- ► Blending neighborhood N = N(t) consists of two arbitrary (but distinct) local systems i and j.

A plane in S describing the common subspace  $S_{\mathcal{N}}=S_i\oplus S_j$  may be found via the SVD:

$$U_{\mathcal{N}}^* \Sigma_{\mathcal{N}} V_{\mathcal{N}} = \mathsf{svd} \big( [(\Phi_i^* + c_i \mathbf{1}_{d_i}^\top) \ (\Phi_j^* + c_j \mathbf{1}_{d_j}^\top)] \big). \tag{1}$$

The common plane has dimension  $d_{\mathcal{N}} \leq d_i + d_j$ , center  $c_{\mathcal{N}} = U_{\mathcal{N}}^* \mathbf{e}_1$ , and orthogonal basis vectors  $\{U_{\mathcal{N}}^* \mathbf{e}_k\}_{k=2}^{d_{\mathcal{N}}}$ .

## Combining Subsystems: Blending

$$P_{i \to \mathcal{N}} = U_{\mathcal{N}} \Psi_i^*$$
$$P_{\mathcal{N} \to i} = \Phi_i U_{\mathcal{N}}^*.$$

Global reduced system:

$$\begin{cases} \dot{\mathbf{x}}(t) = \sum_{i \in \mathcal{N}} w_i(\mathbf{x}, t) P_{i \to \mathcal{N}} f_i(P_{\mathcal{N} \to i} \mathbf{x}) \\ \mathbf{y}(t) = \sum_{i \in \mathcal{N}} w_i(\mathbf{x}, t) h_i(P_{\mathcal{N} \to i} \mathbf{x}) \end{cases}$$
(2)

where  $w_i$  satisfy  $w_i \ge 0, \sum_{i \in \mathcal{N}} w_i = 1$  for all  $\mathbf{x}, t$ .

## Demonstration: Fluid Simulation

- Stable (R<sub>e</sub> = 40) 2-D flow past a stationary cylinder. 61 × 61 grid, D=3721.
- Mixture of implicit and explicit finite difference schemes to numerically integrate the unsteady Navier-Stokes equations in vorticity/stream-function form.
- ► Local POD: snapshots every 30 steps (δt = 10<sup>-3</sup>), n=665 samples.
- Tree:  $\epsilon = 10^{-3}$ , 5 node tree, 3 leaf nodes of dimension d = 3.

- Comparison: Global POD, 5 modes.
- Reduced simulation: switching rule.

# Demonstration: Fluid Simulation

Streamlines illustrating the local POD flow simulation near the beginning (top), after a transition from leaf node model 1 to 2 (middle), and after a transition from leaf node model 2 to 3 (bottom).

## Demonstration: Fluid Simulation

# Evolution of the simulation error for global POD (5 modes) vs. local POD (3 modes):

Vorticity  $\omega$  error (right) and stream function  $\psi$  error (left). Arrows indicate where switching between models occurred in the local POD simulation.

# Summary

- Snapshot-based framework for localized, multiscale reduction
- Statespace decomposed into a collection of planes determined by geometry of empirical trajectories.
- ▶ Defined local POD/balanced-POD projections ⇒ multiscale data-dependent dictionary designed to efficiently encode behavior of a nonlinear system as a collection of simpler systems.
- Global reduced system described by combining local, low-dimensional systems.

#### Advantages:

- Can decompose complex phenomena into multi-resolution hierarchy of simple parts.
- Better approximation at lower complexity: approximating subspaces do not need to capture global behavior.
- Control with simple local controllers ; decentralized possibilities.

Open problem: approximate the local dynamics with simple, easy to evaluate maps.
