Abstract

We show how the results of Karger, Motwani, and Sudan [6] and Blum [3] can be combined in a natural manner to yield an $\tilde{O}(n^{3/14})$-coloring of any $n$-node 3-colorable graph. This improves on the previous best bound of $\tilde{O}(n^{1/4})$ colors [6].

1 Introduction

A $k$-coloring of an $n$-node graph is an assignment of one of $k$ colors to each of the vertices in the graph so that no two adjacent vertices receive the same color. It is well known that the question: “given a graph $G$, can it be colored with $k$ or fewer colors?” is NP-hard for any $k \geq 3$. In addition, recent results show that coloring 3-colorable graphs with 4 or fewer colors is NP-hard [5] and much stronger approximation hardness results are known for the general chromatic number problem [4]. Wigderson [8] describes a very simple method to color any $n$-node 3-colorable graph with $O(\sqrt{n})$ colors. This approximation guarantee was improved by Blum [2, 3] to $\tilde{O}(n^{3/8})$ colors and most recently by Karger, Motwani, and Sudan to $\tilde{O}(n^{1/4})$ colors, where the $\tilde{O}$ notation hides logarithmic factors. In this paper we show how ideas used in the latter two results can be combined to produce a $\tilde{O}(n^{3/14})$-coloring of any $n$-node 3-colorable graph.

2 Preliminaries and Definitions

We will use $N(v)$ to denote the neighborhood of a vertex $v$, and $N(S)$ to denote the neighborhood of a set of vertices $S$: that is, $N(S)$ is the union of the neighborhoods of all vertices in $S$.

It will be convenient to be able to talk about “making progress” towards a desired approximate coloring. Specifically, we will say that finding one of some set of objects “makes progress towards a $C(n)$-coloring”, to mean that if on any 3-colorable $n$-node graph we can guarantee to find one of those objects, then that can be used by a generic algorithm to produce a $C(n)$-coloring of any $n$-node 3-colorable graph. For example, it is not hard to see that finding an independent set of size $n^\alpha$ makes progress towards an $O(n^{1-\alpha})$-coloring, because if we can find such a set of vertices, we can give those vertices one color, remove them from the graph, and recurse on the graph remaining. More generally, the following useful lemma is given in [3].

**Lemma 1 (From Theorem 3 in [3])** Finding any of the following objects in an $n$-vertex 3-colorable graph $G$ makes progress towards an $O(n^\alpha)$-coloring of $G$.

1. An independent or 2-colorable set of size $\Omega(n^{1-\alpha})$.
2. An independent set $S$ having a neighborhood of size $O(|S|n^{1-\alpha})$.
3. Two vertices that share $\Omega(n^{1-2\alpha})$ neighbors in common.

(The most interesting part of the above lemma, item (3), follows from noticing that if two vertices $u$ and $v$ belong to different color classes in a legal 3-coloring of the graph, then their shared neighborhood $S$ belongs to a single color class, and therefore its neighborhood $T$ is 2-colorable. Thus, if $T$ is not 2-colorable then one can merge $u$ and $v$; if $T$ is 2-colorable and large, one can apply item (1); and if $T$ is 2-colorable and small, one can apply item (2). A similar argument is given in more detail in the next section.)

## 3 A simpler result

Before describing the $\tilde{O}(n^{3/14})$-coloring algorithm, we give a simpler argument that yields a $\tilde{O}(n^{2/9})$-coloring. We begin with a theorem from Karger-Motwani-Sudan [6].

**Theorem 1** [6] There is a (randomized) polynomial-time algorithm that will color any 3-colorable graph having maximum degree $\Delta$ with $\tilde{O}(\Delta^{1/3})$ colors.

An examination of the proof of this theorem yields the following corollary:

**Corollary 2** Suppose a 3-colorable graph can have its edges directed so that the maximum outdegree is $\Delta$. Then there is a polynomial-time algorithm to color the graph with $\tilde{O}(\Delta^{1/3})$ colors.

The goal of our algorithm will be to find an independent set of size $\tilde{\Omega}(n^{7/9})$, or else two vertices that share at least $\tilde{\Omega}(n^{5/9})$ neighbors in common, in our given graph $G$. Either way we make progress by Lemma 1. We begin by removing from $G$, one by one, all vertices of degree at most $n^{2/3}$ (in the current $G$). If in doing so we have removed more than half of the
vertices of $G$, then we are done: we simply apply the algorithm of Corollary 2 to the set of $n/2$ vertices removed, and then choose the largest independent set in the coloring produced (which must have size $\Omega((n/2)/(n^{2/3})^{1/3}) = \Omega(n^{1/3})$). Therefore, we may assume below that we now have a graph $G$ on $n/2$ vertices whose minimum degree is greater than $n^{2/3}$.

**Lemma 2** Every vertex in $G$ shares at least $n^{1/3}$ neighbors with some other vertex.

**Proof:** Let $v$ be some vertex in $G$. $v$ has at least $1 + n^{2/3}$ neighbors, each with at least $n^{2/3}$ neighbors in addition to $v$. Thus, there are at least $n^{1/3}$ length-two paths from $v$ that terminate in vertices besides $v$. Therefore at least $n^{1/3}$ of them must terminate at some specific other vertex $u$. It follows that $u$ and $v$ have at least $n^{1/3}$ neighbors in common. ■

We now proceed as follows, using an argument similar to that for item (3) of Lemma 1. Let $u$ and $v$ be two vertices whose shared neighborhood $S = N(u) \cap N(v)$ has size at least $n^{1/3}$, and let $T$ be the neighborhood of $S$. Notice that if $u$ and $v$ have different colors in the optimum coloring, then $S$ is monochromatic and therefore $T$ may be 2-colored. Thus, if we find that $T$ is not 2-colorable, we know $u$ and $v$ must have the same color in the optimum coloring and so we can merge them and start over on a graph of one less vertex.

Also, if we find that $T$ is 2-colorable and $|T| \ge n^{7/9}$, then we can make progress towards an $O(n^{7/9})$-coloring by Lemma 1. Therefore, we may assume below that $|T| < n^{7/9}$.

We now show that there must be two vertices in $S$ that share at least $n^{2/3}$ neighbors in common. Let $S'$ be an arbitrary subset of $S$ of size $2n^{1/3}$ and suppose for contradiction that no two vertices of $S'$ share $n^{2/3}$ neighbors. Since each vertex of $S'$ has degree at least $n^{2/3}$ it follows that each vertex of $S'$ has at least $n^{2/3} - 2n^{1/3}(n^{5/9}) = \frac{1}{2}n^{2/3}$ neighbors not in common with any other vertex of $S'$. Therefore, $|N(S')| \ge 2n^{1/3} \cdot \frac{1}{2}n^{2/3} = n^{7/9}$. But this contradicts our assumption that $|T| < n^{7/9}$. Therefore, there must be two vertices in $S'$ that share at least $n^{2/3}$ neighbors in common, so we can make progress by Lemma 1.

### 4 The $\tilde{O}(n^{3/14})$-coloring

We will need the following definitions from [3]. Let $d(v)$ denote the degree of vertex $v$. If $S$ and $T$ are sets of vertices, let $d_T(v) = |N(v) \cap T|$, and let $D_T(S) = \sum_{v \in S} d_T(v)$. In other words, $D_T(S)$ is the number of edges between $S$ and $T$, double-counting for edges whose endpoints are in both sets. Write $D_V(S)$, which is just the sum of degrees of vertices in $S$, as $D(S)$. Define (as before) $N(S) = \bigcup_{v \in S} N(v)$.

Let $\delta = \delta(n) = \frac{1}{3 \log n}$. We define $I_j = \{v \in V \mid d(v) \in [(1 + \delta)^j, (1 + \delta)^{j+1}]\}$ for $j = 0, 1, 2, \ldots$. That is, we divide the set of vertices of degree at least 1 into bins $I_j$ so that in each bin, the ratio of the degrees of any two vertices is less than $(1 + \delta)$. For a set of vertices $S$, let $N_i(S) = \{v \in N(S) \mid d_S(v) \in [(1 + \delta)^i, (1 + \delta)^{i+1}]\}$ for $i = 0, 1, 2, \ldots$. In other words, $N_i(S)$ is the subset of vertices in $N(S)$ that are hit by at least $(1 + \delta)^i$ and less that $(1 + \delta)^{i+1}$ edges from $S$. 

3
We now present slightly simplified versions of three theorems from [3]. Let \( R \) (red) be a color class in a correct 3-coloring of \( G \) such that \( D(R) \geq \frac{1}{3} D(V) \), or equivalently, \( D(R) \geq \frac{1}{2} D(V - R) \). Notice that \( D(R)(V - R) = D(R) \) so \( D(R)(V - R) \geq \frac{1}{2} D(V - R) \); or in words: our definition of “red” is such that on average, a non-red vertex has at least half its neighbors colored red.

**Theorem 3 ([3])** Given a 3-colorable \( n \)-vertex graph \( G = (V, E) \), there is some \( v \in R \) and some \( j \in \{0, 1, \ldots, \log_{1+\varepsilon} n \} \) such that the set \( S = N(v) \cap I_j \) satisfies the following:

1. \(|S| \geq \delta^2 D(R)/(|R| \log_{1+\varepsilon} n)\),
2. \( D_R(S) \geq \frac{1}{2}(1 - 3\varepsilon) D(S)\).

In other words, for some \( v \in R \), the set \( S = N(v) \cap I_j \) is reasonably large and almost half of the edges incident to it have their other endpoint in \( R \).

The next theorem considers the neighbors of \( S \) and states that for some \( i \), the set \( T = N_i(S) \) is nearly half red in the correct 3-coloring. This is useful because given a set of vertices \( T \) which contains an independent set of size at least \( \frac{1}{2}(1 - \frac{1}{\log n})|T| \), one can find an independent set of size at least \( |T|/\log |T| \) using an algorithm of Bar-Yehuda and Even [1] and (independently) Monien and Speckenmeyer [7]. Thus, if \( T \) is sufficiently large we can make progress towards our desired coloring.

**Theorem 4 ([3])** Given an \( n \)-vertex 3-colorable graph \( G = (V, E) \), and \( \lambda \in [0, 1] \):

For any set \( S \) such that \( D_R(S) \geq \lambda D(S) \), there must exist some \( i < \log_{1+\varepsilon} n \) such that the set \( T = N_i(S) \) satisfies the following:

1. \( D_T(S) \geq \delta D_R(S)/\log_{1+\varepsilon} n \),
2. \( |T \cap R|/|T| \geq (1 - 2\varepsilon)\lambda \).

The final theorem from [3] that we will use implies that if the set \( T \) in the above theorem is much smaller than what one would expect given the number of edges between \( S \) and \( T \), then one can make progress towards the desired coloring.

**Theorem 5 ([3])** Given sets of vertices \( S \) and \( T \) in an \( n \)-vertex 3-colorable graph \( G \), such that

1. \( S \) is 2-colored under some legal 3-coloring of \( G \),
2. \( D_T(S) = \Omega(|S|n^{1-2\varepsilon} \log^2 n) \), and
3. \([D_T(S)]^3 = \Omega \left( |S| + \max_{v \in S} d_T(v) \right) \times \left( |S||T|^2 n^{1-2\varepsilon} \log n + |T||S|^2 n^{2-4\varepsilon} \right)\),

we can make progress towards an \( O(n^\varepsilon) \)-coloring of \( G \).

We now combine these theorems with the results of KMS [6] to achieve an \( \tilde{O}(n^{3/14}) \)-coloring of any \( n \)-vertex 3-colorable graph.
Theorem 6  There is a polynomial time algorithm to color any $n$-vertex 3-colorable graph with $\tilde{O}(n^{3/14})$ colors.

Proof:

As in the algorithm of the previous section, we begin by removing all low-degree vertices from $G$, where “low degree” now means degree at most $n^{3/14}$. If we are able to remove more than $n/2$ vertices we make progress using Corollary 2 as before. Thus, we may assume from now on that all vertices in $G$ have degree at least $n^{3/9} = 1/4$.

Theorems 3 and 4 imply that for some vertex $v$ and some indices $i, j \in \{0, \ldots, \log_2 n\}$, the sets $S = N(v) \cap I_j$ and $T = N_i(S)$ satisfy the following properties.

$$|T \cap R|/|T| \geq (1 - 2\delta)(1 - 3\delta)\frac{1}{2} \geq \frac{1}{2}(1 - \frac{1}{\log n})$$

and

$$D_T(S) = \Omega(\delta D(S)/\log_2 n)$$

$$= \Omega(\delta n^{9/14}|S|/\log n). \text{ (because of the minimum degree) (1)}$$

(In the algorithm, we simply try all choices of $v, i, j$.)

Since $T$ has an independent set of size at least $\frac{1}{2}|T|(1 - \frac{1}{\log n})$, a vertex-cover approximation algorithm of Bar-Yehuda and Even [1] and Monien and Speckenmeyer [7] (or see Lemma 11 in [3]) will find in $T$ an independent set of size $|T|/\log |T|$. Therefore, we have made progress towards our desired coloring if $|T| = \Omega(n^{11/14})$.

If on the other hand $|T| = o(n^{11/14})$, we will make progress using Theorem 5 as follows. First, $S$ satisfies property (1) of the theorem since it is part of the neighborhood of some node. Second, property (2) is satisfied easily by Equation 1 above (with $\Omega(n^{1/14})$ to spare).

The key constraint is property (3), which is what results in the specific exponent of $3/14$. Define $\hat{d}$ to be the average degree of vertices in $S$. In fact, by definition of $S$, all vertices in $S$ have nearly the same degree, so $\max_{v \in S} d_T(v) \leq \max_{v \in S} \hat{d} = O(\hat{d})$. By Equation 1 we have that $D_T(S) = \tilde{\Omega}(D(S)) = \tilde{\Omega}(\hat{d}|S|)$. Thus, we can reduce property (3) to showing that:

$$[\hat{d}|S|^3 = \tilde{\Omega}(\hat{d}^2 n^{30/14} + |S|^2 n^{27/14})].$$

This can now easily be verified by using the fact that $|S|$ and $\hat{d}$ are both $\tilde{\Omega}(n^{9/14})$. (For $|S|$, this fact follows from item 1 of Theorem 3.)
