- Circuit Complexity

Big picture in complexity

- E.g., Would like a complete map of complexity?
- Unfortunately: only two tools so far - Algorithms & Diagonalization.
- Diagonalization can prove:
  - Problems undecidable.
  - Space hiearchy, time hierarchy.
  - Ladner's theorem (between any two classes is an infinitely dense hierarchy).
  - But can it resolve NP $\stackrel{?}{=}$ P?

Aside: Bird's eyeview of Ladner's theorem

- Suppose P $\neq$ NP.
- Let $L_1 \in$P and L_2 be NP-complete.
- Let $n_1 = 1$ and $n_i = 2^{n_{i-1}}$.
- Let $L = L_1$ for strings of length $[n_{i-1}, n_i)$ for odd i, and $L = L_2$ for strings of length $[n_{i-i}, n_i)$ for even i.
- $L \in$P? Probably not.
- Is L NP-complete? Probably not.
- Ladner's theorem picks a more careful choice of n_i's (by "lazy diagonalization"), to eliminate the "Probably's" above.

- Won't cover theorem in detail.

Power of diagonalization

- Can it resolve NP $\stackrel{?}{=}$ P?
- Question raised in the seventies.
- Baker-Gill-Solovay: No!
- Err.... some caveats ....

Relativization

Defn: Let C be a complexity class of languages decidable with machines having a certain resource bound. Let A be any language. Then C^A is the set of languages accepted by oracle machines, with the same (similar?) resource bound as machines in C, having access to oracle for A.

Warning: Not really a definition!

Defn: P^A is the set of all languages accepted by deterministic polynomial time oracle Turing machines with access to oracle for A.

Defn: NP^A is the set of all languages accepted by non-deterministic polynomial time oracle Turing machines with access to oracle for A.

B-G-S Proposition

Prop: If diagonalization shows $C_1 \not\subset C_2$, then for every A, $C_1^A \not\subset C_2^A$.

Jargon: $C_1 \not\subset C_2$ relativizes.

Proof (of Prop/Jargon):

- Exists machine in C_1 that can simulate any machine in C_2. (Since diagonalization works.)
- Augment this machine into an oracle machine.
- Machine now shows that C_1^A diagonalizes C_2^A.

BGS Lemmas

Lemma 1 There exists an oracle A such that $\mathsf{NP}^A = \mathsf{P}^A$.

Proof: Take some language that is sufficiently powerful. Example: Let A be any PSPACE-complete language. Then $\mathsf{NP}^A = \mathsf{NPSPACE} = \mathsf{PSPACE} = \mathsf{P}^A$.

BGS Lemmas

Lemma 2 There exists an oracle B such that $\mathrm{NP}^B \neq \mathrm{P}^B$.

Proof:

- Insert proof here.

BGS Warnings

- Proof makes sense only when specialized (to say P vs. NP).
- Otherwise, it is pedagogy, not mathematics.
- Only rules out very specific proofs. Minor variations not accepted!
- Often misinterpreted, mispresented, misrepresent etc.
- Alternate approach: Try combinatorics.

Circuits

Defn; Circuit over $\{\mathrm{Not}, \vee, \wedge\}$ is a directed acyclic graph, with nodes of one of the following types:

- Input Nodes: In-degree zero, labelled with el't of $\{x_1, \ldots, x_n\}$.
- Computation nodes: Labelled by one of $\{\mathrm{Not}, \vee, \wedge\}$, with Not nodes having in-deg. one, and others having in-deg. two.
- m-Output nodes: In-degree one, Out-degree zero, labelled by distinct elements of $\{y_1, \ldots, y_m\}$.

Circuit computes function $f : \{0,1\}^n \to \{0,1\}^m$ in the natural way: Given assignment

in $\{0,1\}$ to $x_1, \ldots, x_n$, propagate assignment along circuit (labelling vertices as appropriate functions of incoming edges, and edges as equal to the label of the vertices they come from) and then reading off the assignment to the m output vertices $y_1, \ldots . y_m$ in order.

Non-uniform models of computation

- Circuits only compute functions on fixed input length. How to compare their power vs. that of a Turing machine?
- Idea: Use a family of circuits $\{C_n\}$, where $C_n : \{0,1\}^n \to \{0,1\}$.
- $\{C_n\}$ decides L if for every n, $L \cap \{0,1\}^n = C_n^{-1}(1)$.
- Circuit complexity of language L is the function $f(n) = |C_n|$, where C_n is smallest circuit to accept $L \cap \{0,1\}^n$.
- What languages can be computed by family of polynomial sized circuits? Exponential sized circuits? Doubly exponential sized circuits?

Non-uniformity

Jargon: Ability to do completely different things on different inputs in referred to as non-uniformity.

Other models:

- Formulae: Circuits where DAG is a tree (root = uinique output).
- Branching programs: Diff. model: given by DAG, with one source, two sinks (labelled 0/1), every node (except sinks) have out-deg. 2 and are labelled by element of $\{x_1, \ldots, x_n\}$. Edges labelled $0/1$. Assignment to $x_1, \ldots, x_n$ specifies path from source to sink. Function value = label of sink.

Captured broadly by "two input machine with advice". $M(x,y)$ is a two-input machine. Advice is a sequence of strings $a = (a_1, \ldots, a_n, \ldots,)$ with $a_n \in \{0,1\}^{\ell(n)}$.

If M is in class $\mathcal{C}$ and $L = M$ with advice a, then L is said to be in $\mathcal{C}/_\ell$. Most relevant class $P/_{\text{poly}}$.

$\mathcal{C} \subseteq \mathcal{C}/_\ell$ and so P $\subseteq$ P$/_{\text{poly}}$.

P$/_{\text{poly}}$ = all languages with poly-sized circuit complexity.

Let $M(x,y)$ compute output of circuit y on input x - decides circuit y.

On the other hand, any advice a_n can be hardwired into circuit C_n and then it suffices to simulate a Turing Machine computation with a circuit. Can do so trivially with

quadratic slowdown; Much harder to do this with poly-logarithmic slowdown; but can be done.

Some basic hopes/intuitions

- Size of circuit (# of nodes) $\approx$ running time?
- Width of branching program $\approx$ space complexity?
- Er ... every language has a circuit family of exponential size ($|C_n| = 2^{O(n)}$; and a branching program of constant width.
- Every unary languge has a constant sized circuit! (including undecidable ones).
- Highly contradictory? Refinement of belief: For NP-complete languages, circuit complexity is exponential.

Circuits and combinatorics

- Set of functions computable by circuits of given size may yield to combinatorial methods. E.g., it is easy to show that $\exists$ functions that require circuits of size $2^{\Omega n}$ etc.
- But give an explicit function? Of moderate-low uniform complexity? Hard. Best uniform to non-uniform contrast: There exists a function in doubly exponential time that does not have polynomial sized (or even sub-exponential sized) circuits. (Kannan.)
- For functions in PSPACE (or even EXP), best known lower bound on circuit size ...

$4.5n$. for formulae, n^3, and for branching programs n^2 ...
