

Computing Beyond Silicon Summer School

Physics becomes the computer

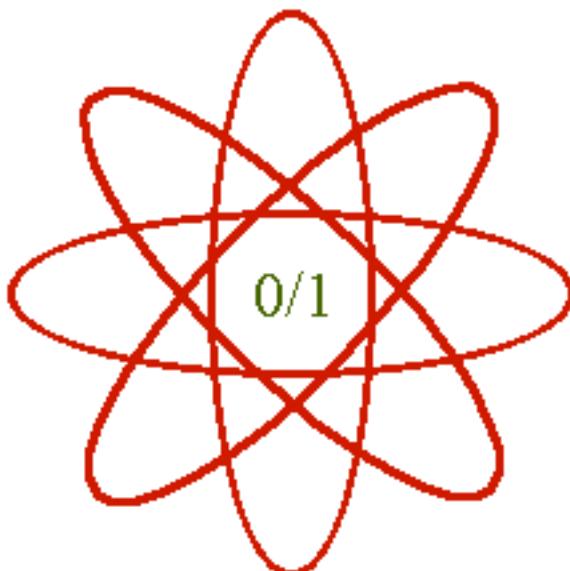

Norm Margolus

Physics becomes the computer

Emulating Physics

- » *Finite-state, locality, invertibility, and conservation laws*

Physical Worlds

- » *Incorporating comp-universality at small and large scales*

Spatial Computers

- » *Architectures and algorithms for large-scale spatial computations*

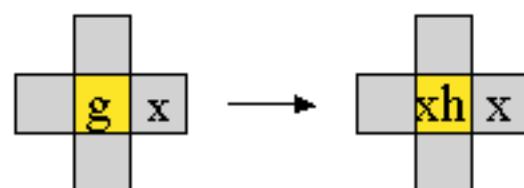

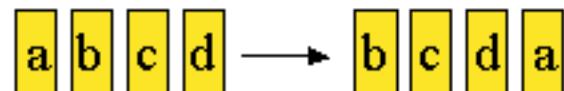

Nature as Computer

- » *Physical concepts enter CS and computer concepts enter Physics*

Review: CA's with conservations

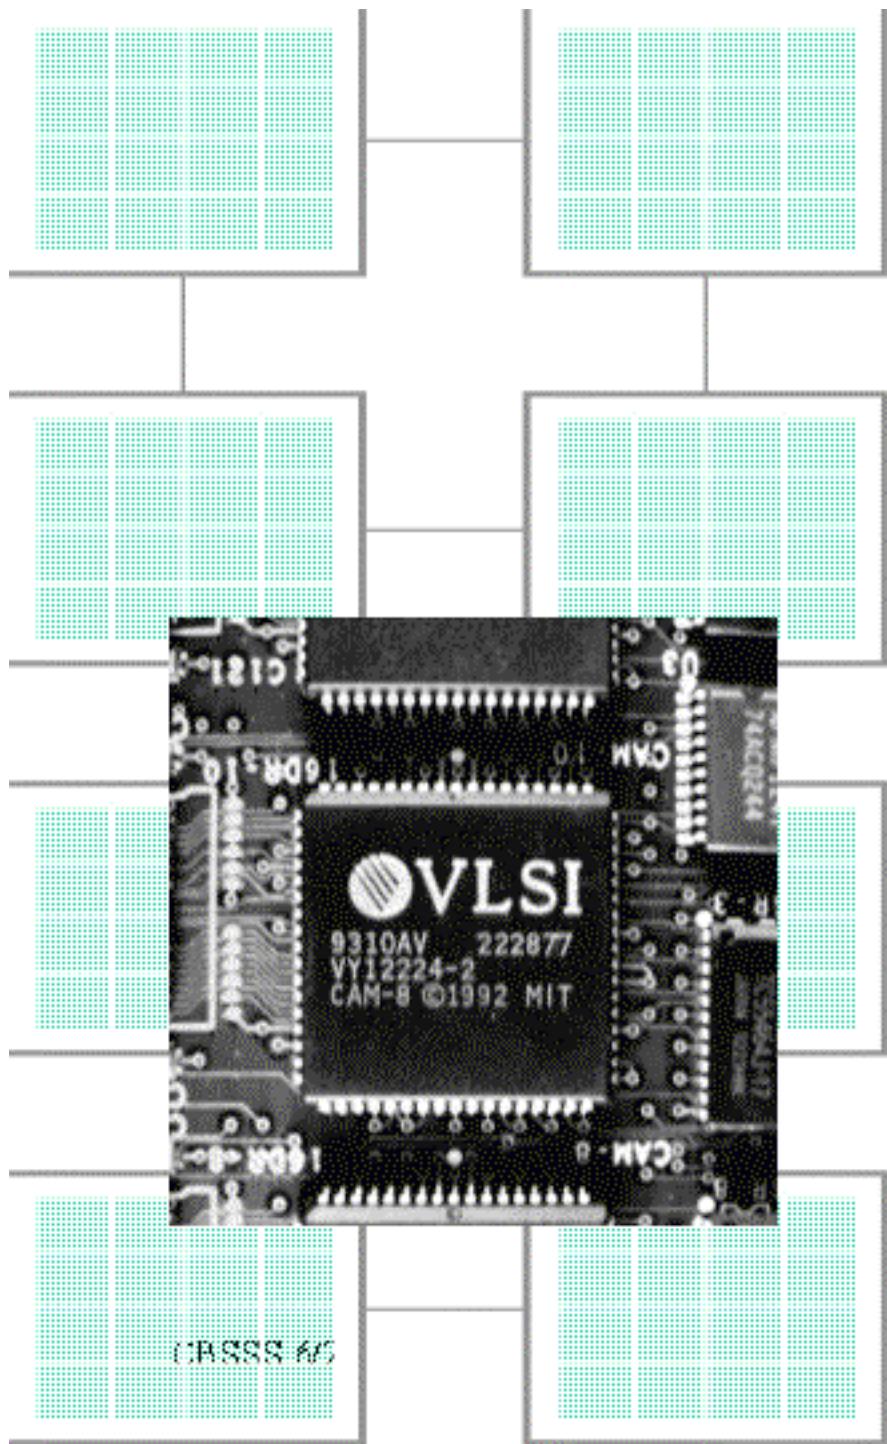

To make reversibility and other conservations manifest, we employ a multi-step update, in each step of which either

1. *The data are rearranged without any interaction, or*
2. *The data are partitioned into disjoint groups of bits that change as a unit. Data that affect more than one such group don't change.*

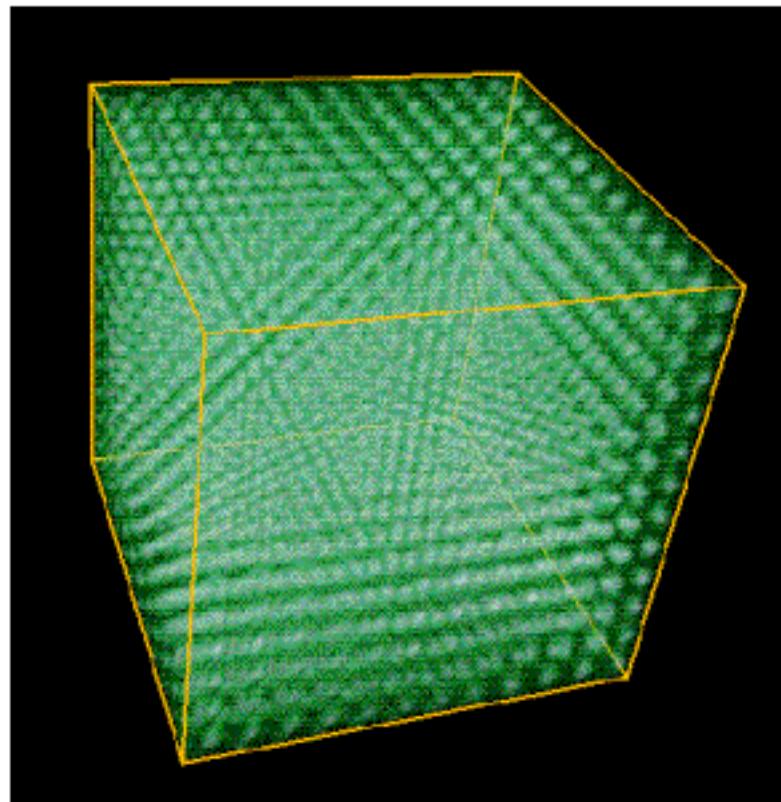

We would like to be able to study large-scale computations with this kind of conservation-friendly format, which allows them to map efficiently onto microscopic physics, and also allow them to have interesting macroscopic behavior.

Spatial Computers

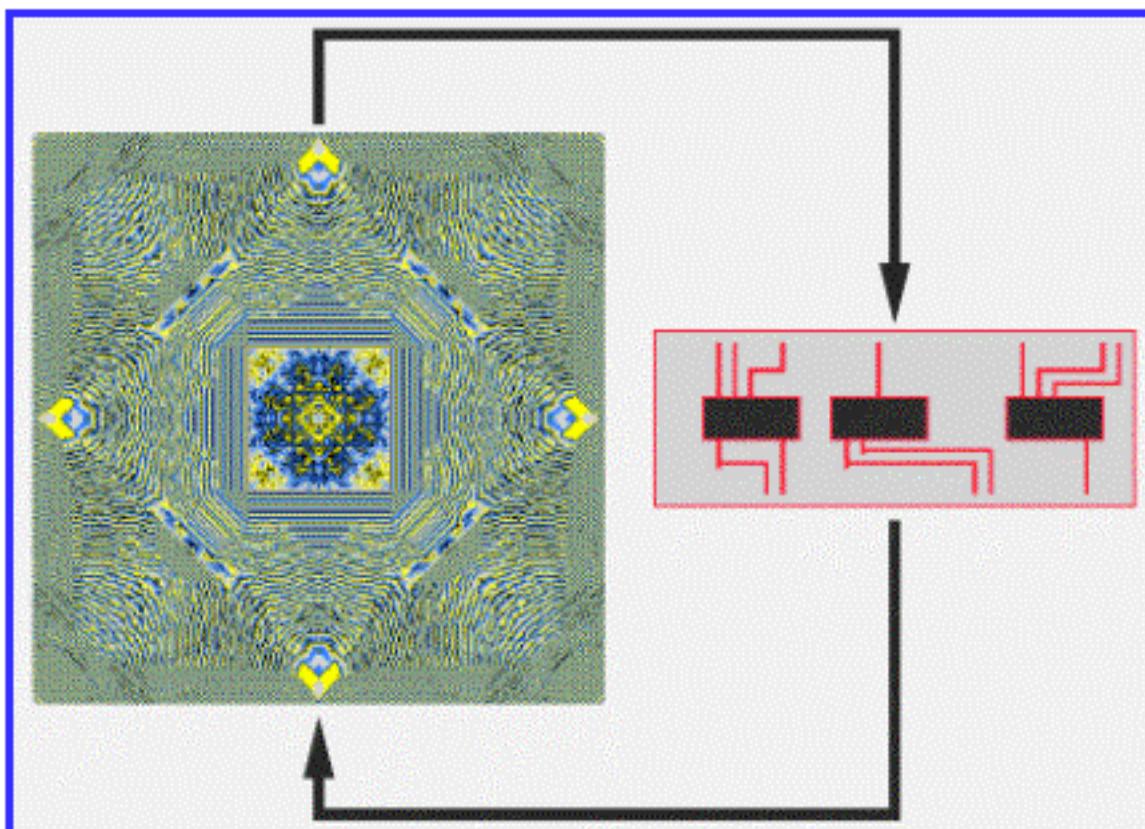

Spatial Computers

- Finite-state computations on lattices are interesting
- Crystalline computers will one day have highest performance
- Today's ordinary computers are terrible at these computations

We may one day compute with regular crystals of atoms.

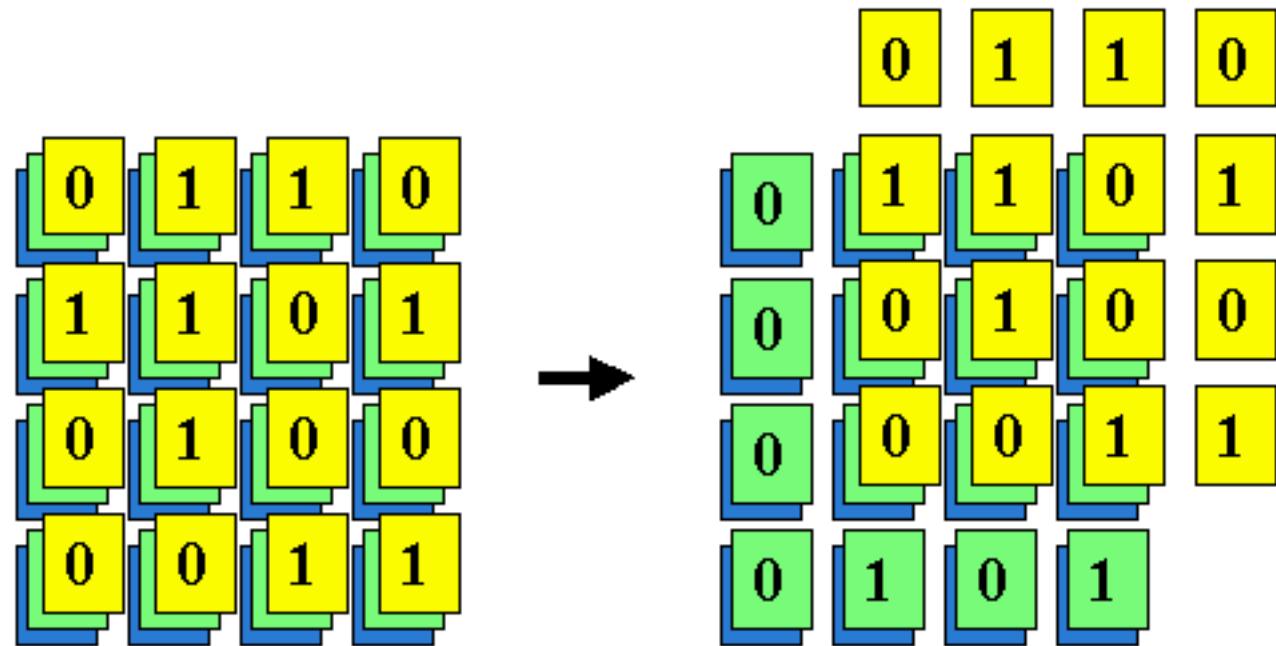

CAMs 1 to 6

- Tom Toffoli and I wanted to see CA-TV
- Stimulated by new rev rules
- Rule = a few TTL chips!
- Later, rule = SRAM LUT
- LGA's needed more “serious” machine!

CAM-8 Programming Model

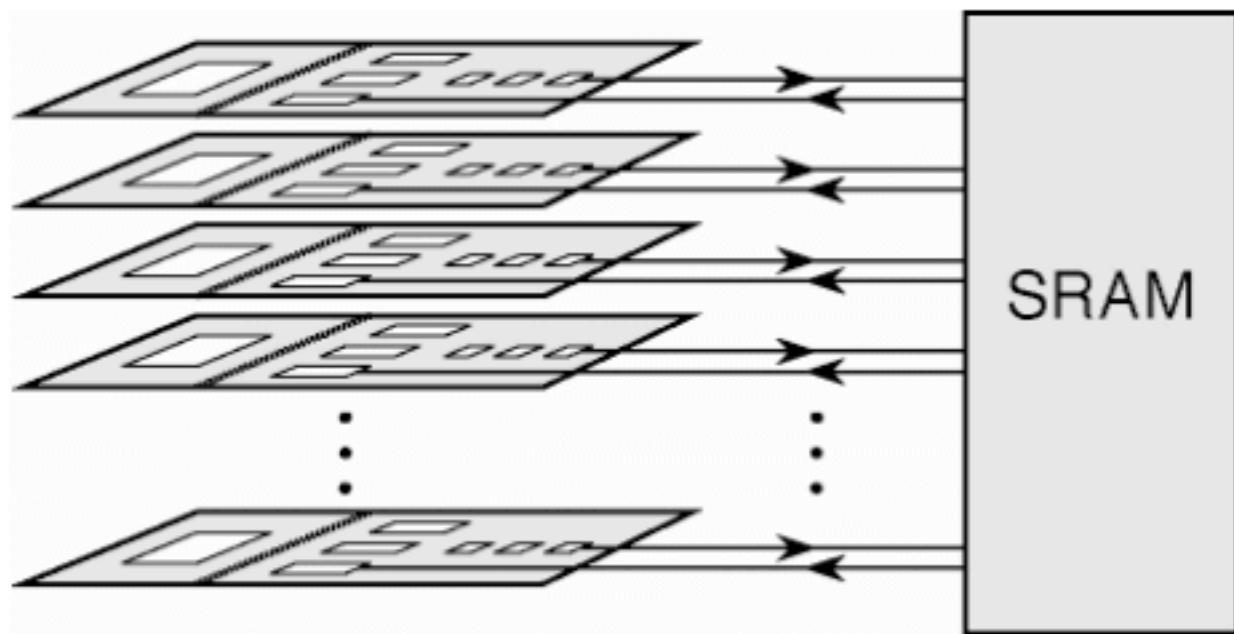

*Data
movement
step:*

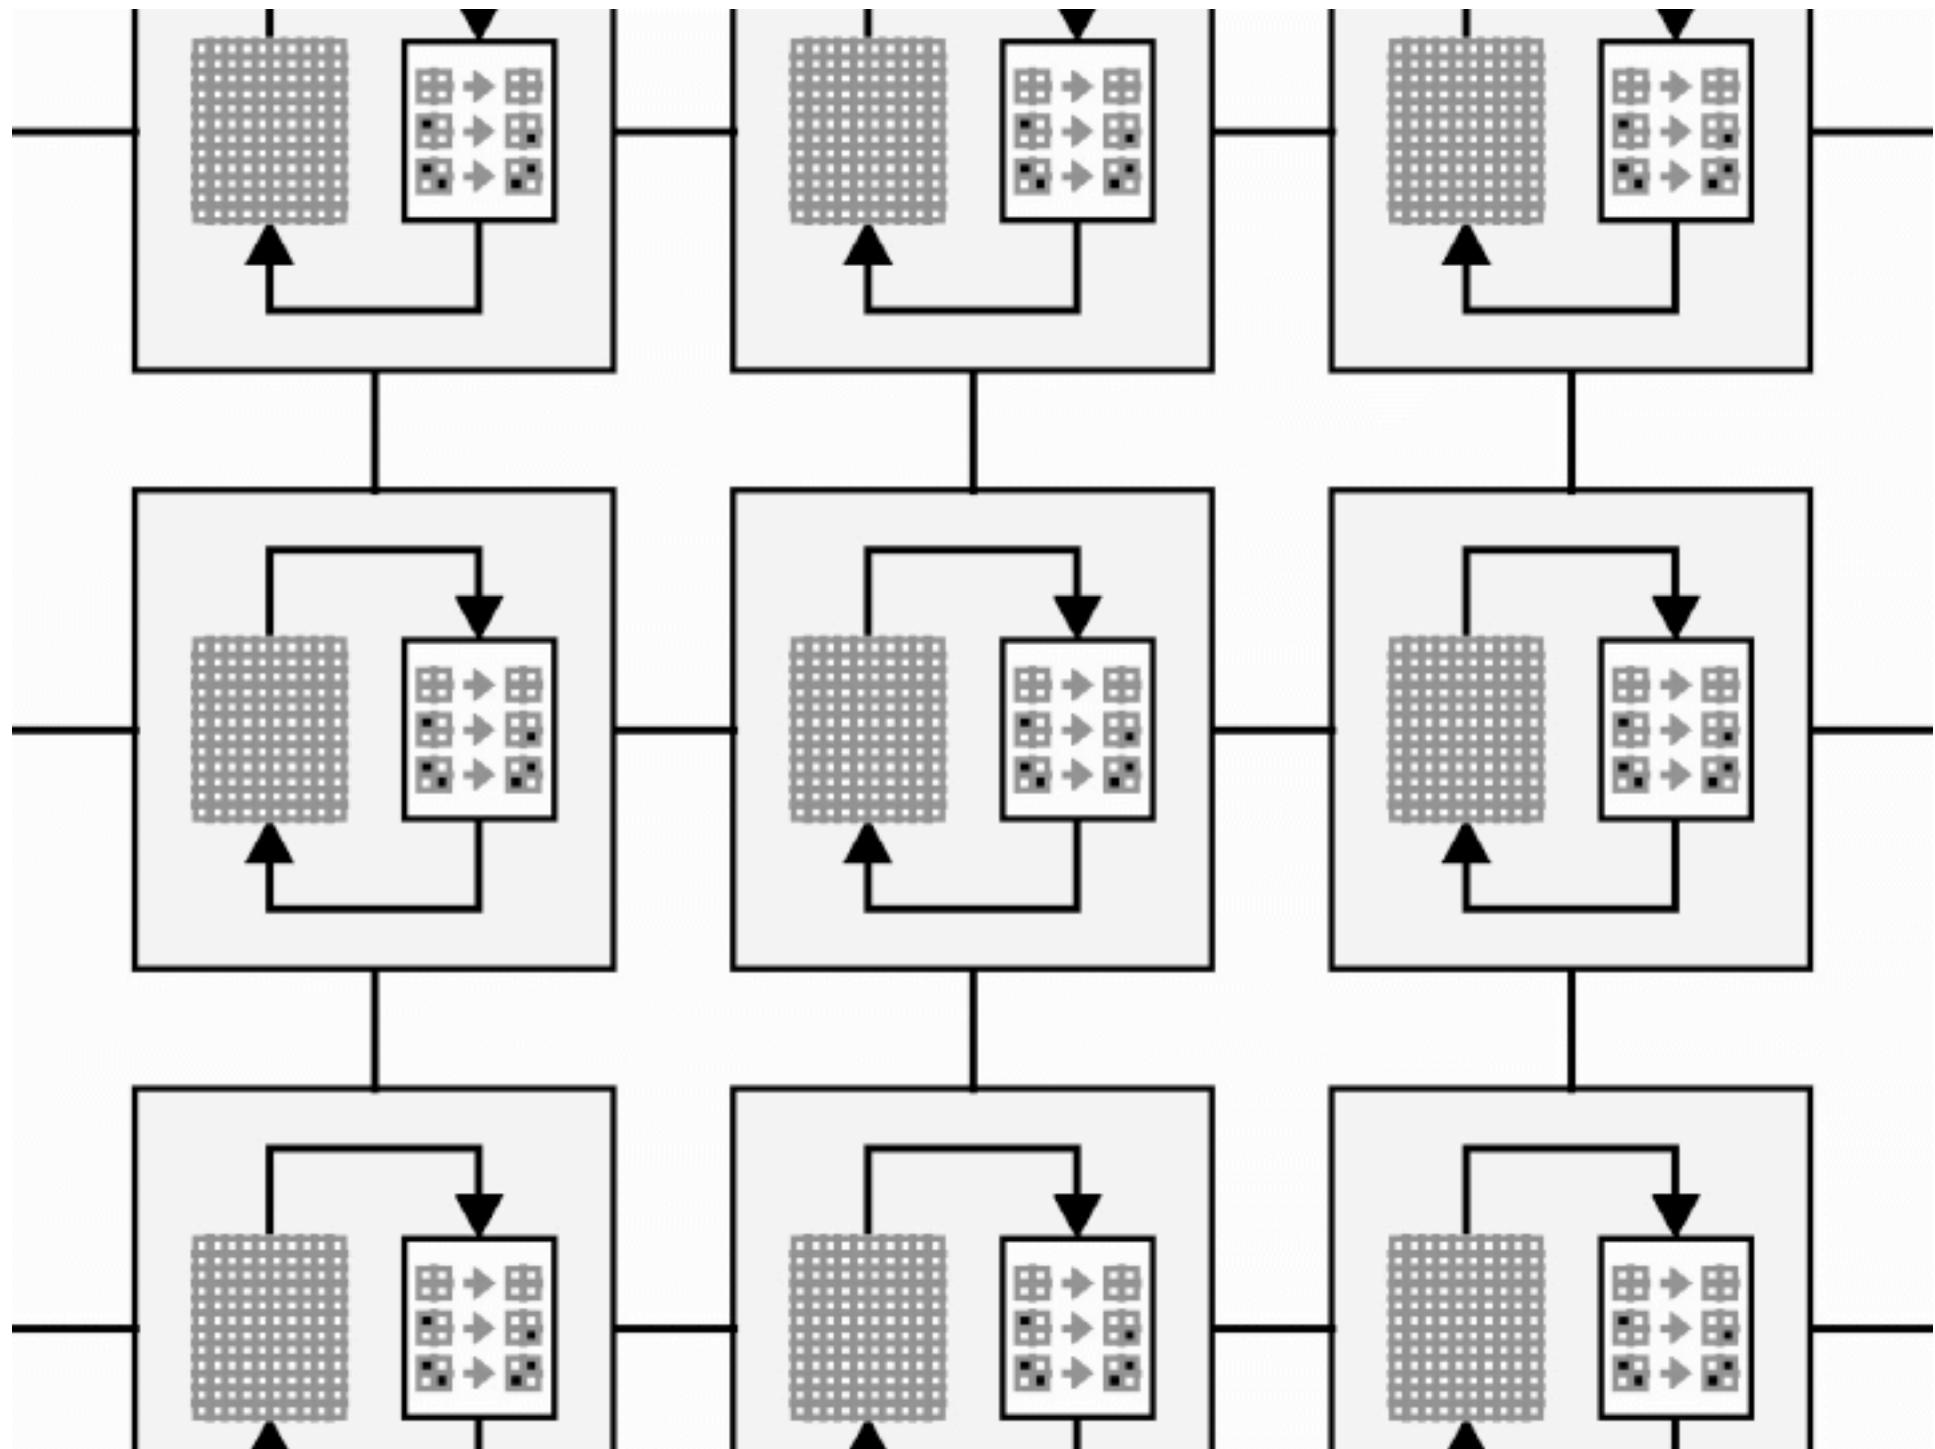

*Site
update
step:*

CAM-8 node

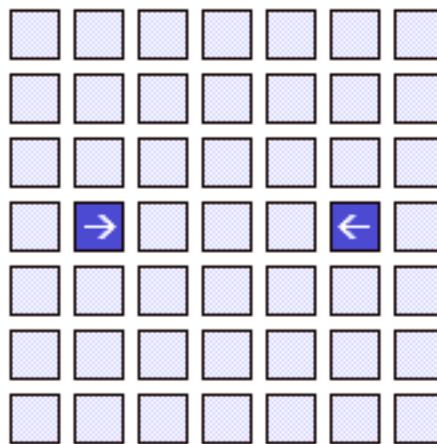

- maps directly onto programming model (*bit fields*)
- 16-bit lattice sites (use internal dimension to get more)
- each node handles a chunk of a larger space

Lattice example

```
/* Four direction lattice gas */

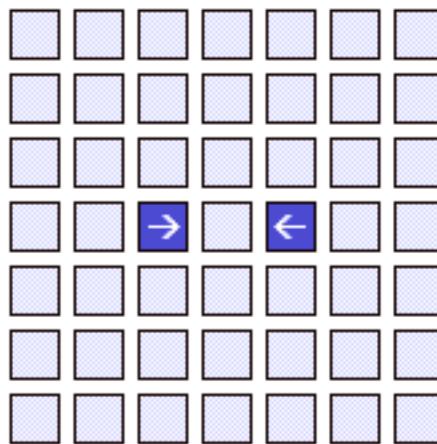

2D-square-lattice {512 512}
create-bit-planes {N S E W}
define-step
    shift-planes { (N,0,-1) (S,0,1)
                    (E,1,0) (W,-1,0) }
    for-each-site
        if {N==S && E==W}
            xchng(N,E); xchng(S,W)
        endif
    end-site
end-step
```

Lattice example

```
/* Four direction lattice gas */

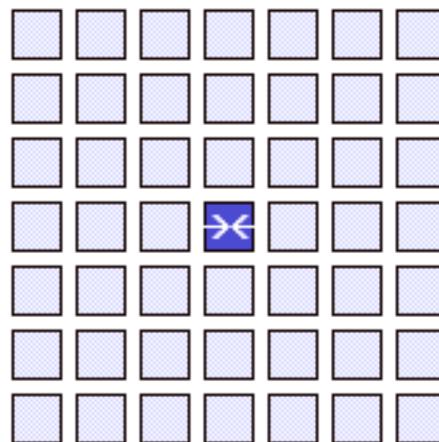

2D-square-lattice {512 512}
create-bit-planes {N S E W}
define-step
    shift-planes { (N,0,-1) (S,0,1)
                    (E,1,0) (W,-1,0) }
    for-each-site
        if {N==S && E==W}
            xchng(N,E); xchng(S,W)
        endif
    end-site
end-step
```

Lattice example

```
/* Four direction lattice gas */

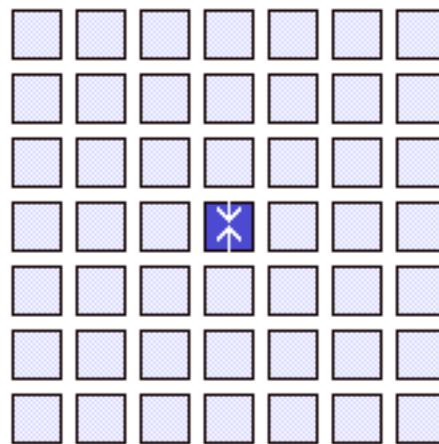

2D-square-lattice {512 512}
create-bit-planes {N S E W}
define-step
    shift-planes { (N,0,-1) (S,0,1)
                  (E,1,0) (W,-1,0) }
    for-each-site
        if {N==S && E==W}
            xchng(N,E); xchng(S,W)
        endif
    end-site
end-step
```

Lattice example

```
/* Four direction lattice gas */

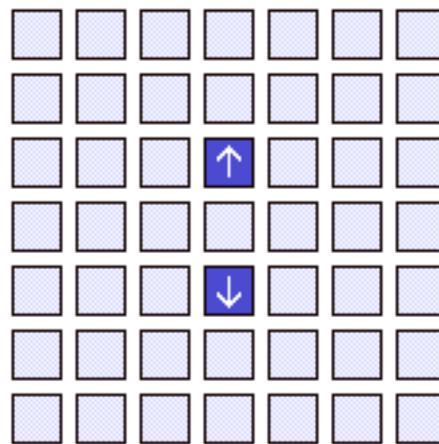

2D-square-lattice {512 512}
create-bit-planes {N S E W}
define-step
    shift-planes { (N,0,-1) (S,0,1)
                    (E,1,0) (W,-1,0) }
    for-each-site
        if {N==S && E==W}
            xchng(N,E); xchng(S,W)
        endif
    end-site
end-step
```

Lattice example

```
/* Four direction lattice gas */

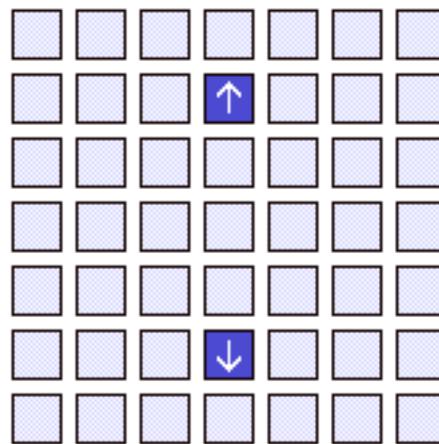

2D-square-lattice {512 512}
create-bit-planes {N S E W}
define-step
    shift-planes { (N,0,-1) (S,0,1)
                    (E,1,0) (W,-1,0) }
    for-each-site
        if {N==S && E==W}
            {xchng(N,E); xchng(S,W) }
        endif
    end-site
end-step
```

Lattice example

```
/* Four direction lattice gas */

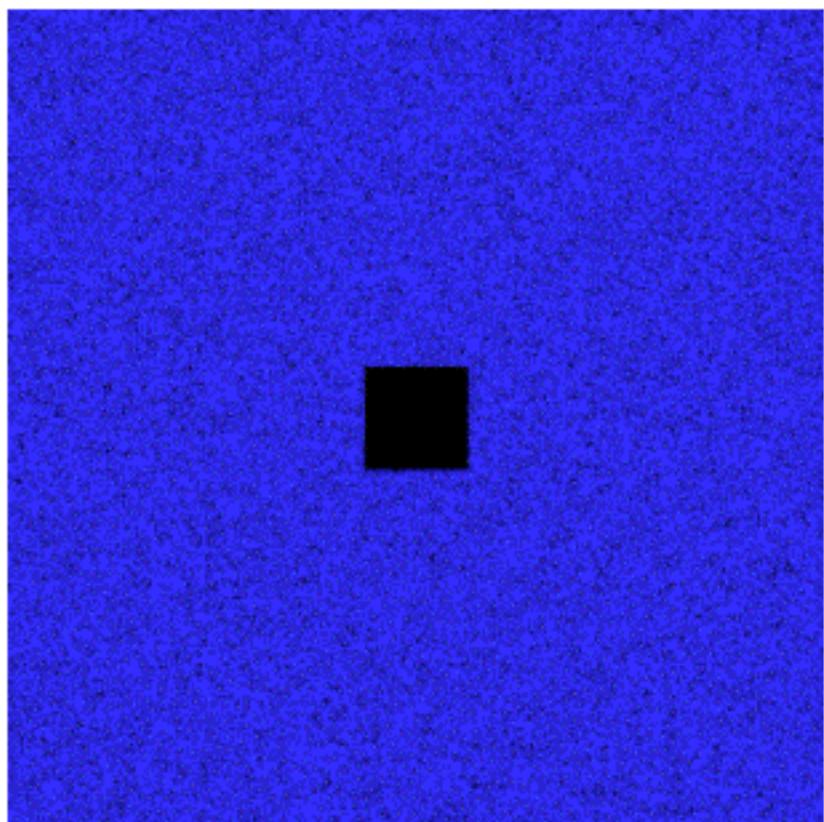

2D-square-lattice {512 512}
create-bit-planes {N S E W}
define-step
    shift-planes { (N,0,-1) (S,0,1)
                    (E,1,0) (W,-1,0) }
    for-each-site
        if {N==S && E==W}
            {xchng(N,E); xchng(S,W) }
        endif
    end-site
end-step
```

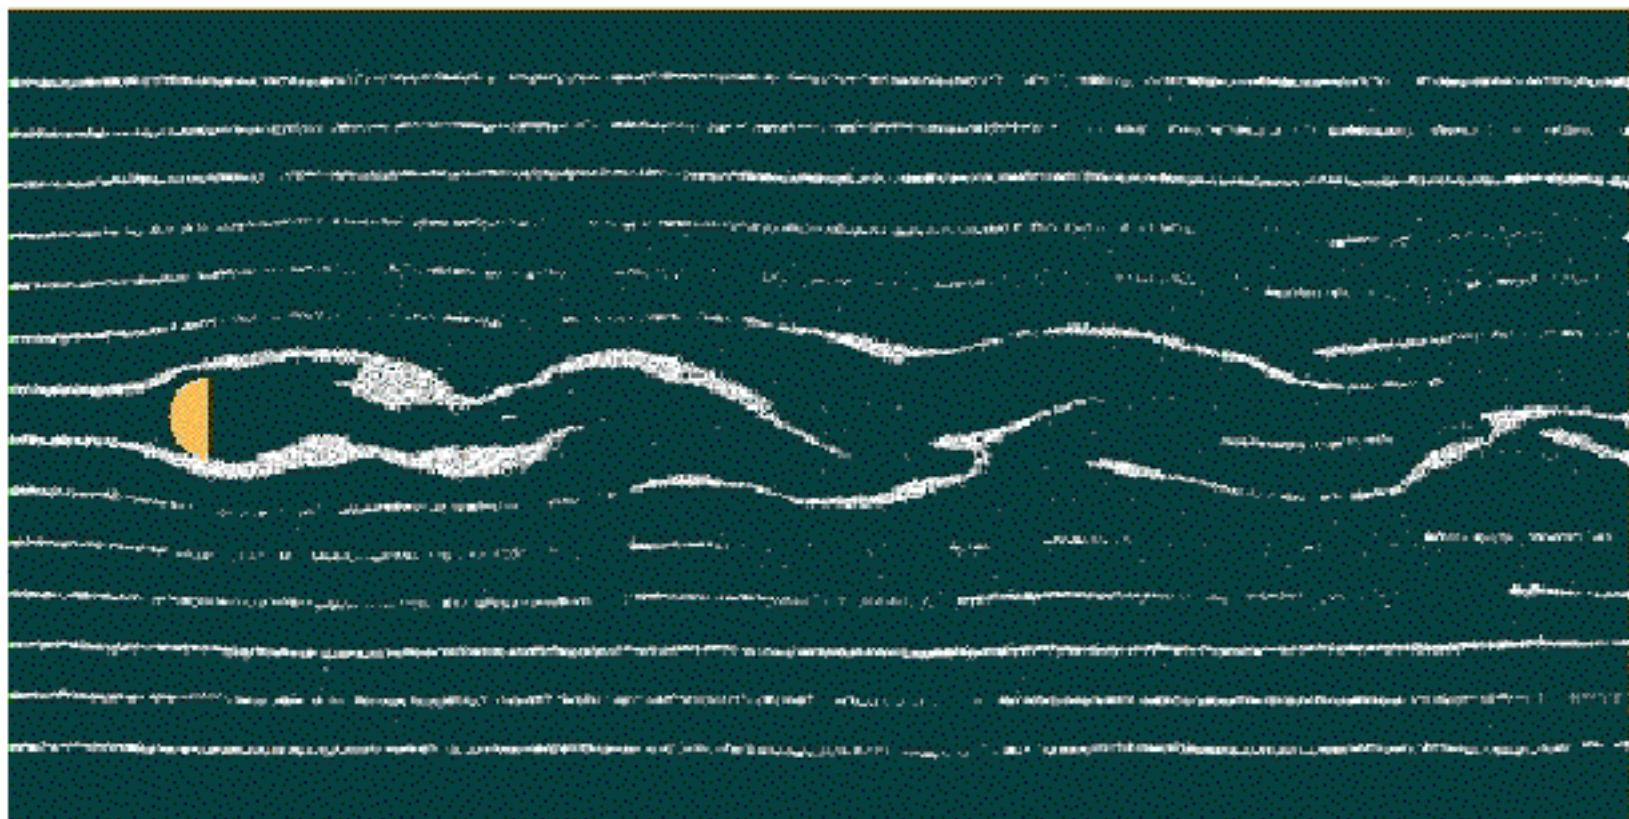

Lattice example

```
/* Four direction lattice gas */

2D-square-lattice {512 512}
create-bit-planes {N S E W}
define-step
    shift-planes { (N,0,-1) (S,0,1)
                  (E,1,0) (W,-1,0) }
    for-each-site
        if {N==S && E==W}
            {xchng(N,E); xchng(S,W) }
        endif
    end-site
end-step
```

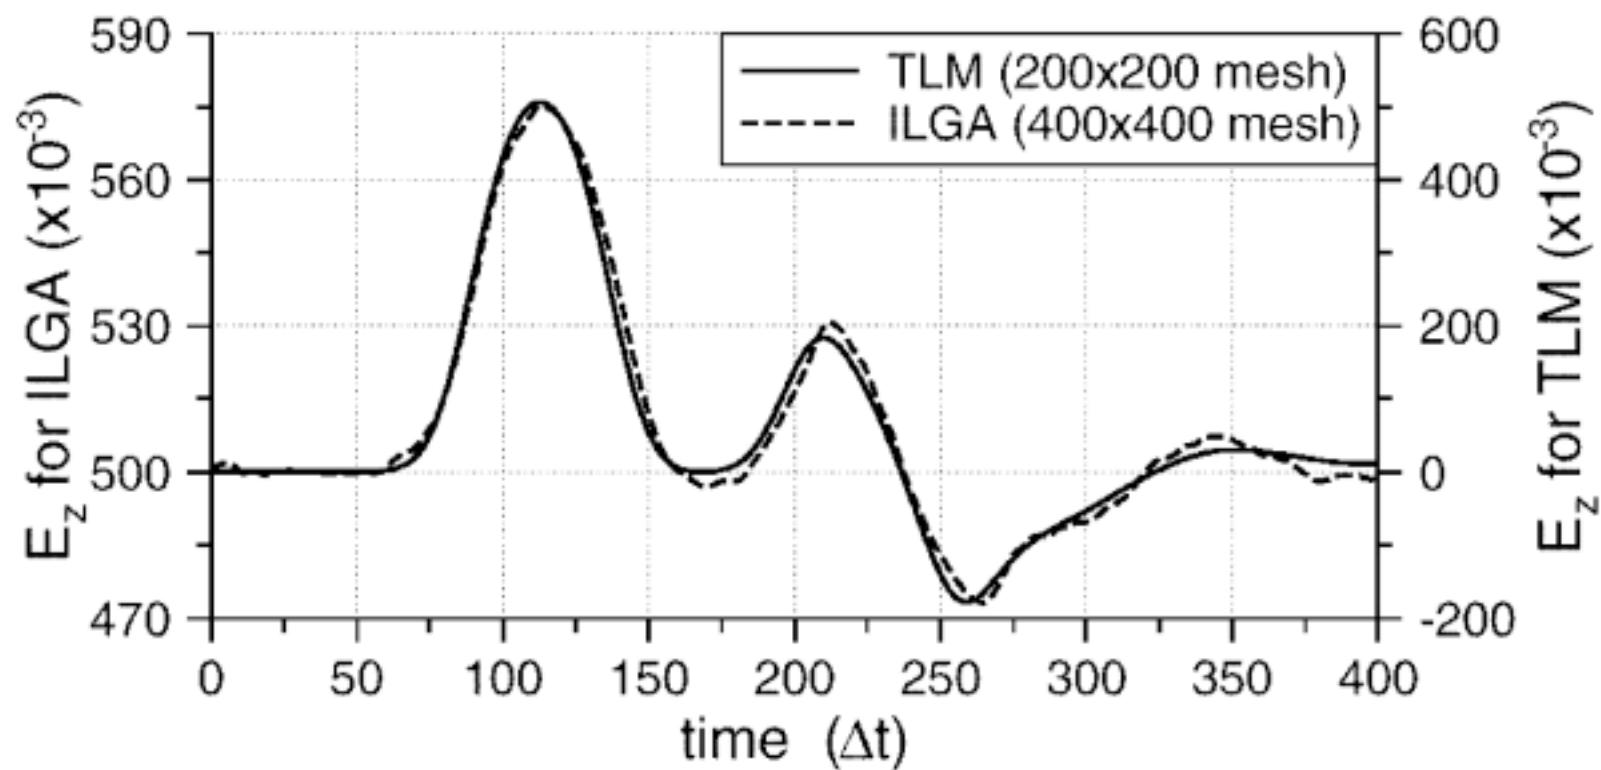

CAM-8: discrete hydrodynamics

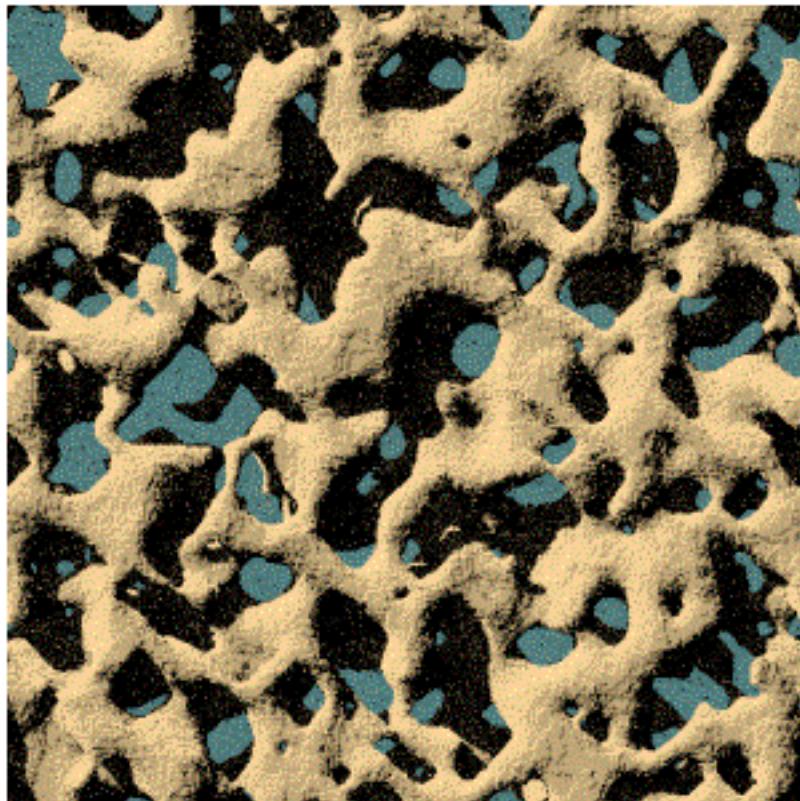

Six direction LGA flow past a half-cylinder. System is $2K \times 1K$.

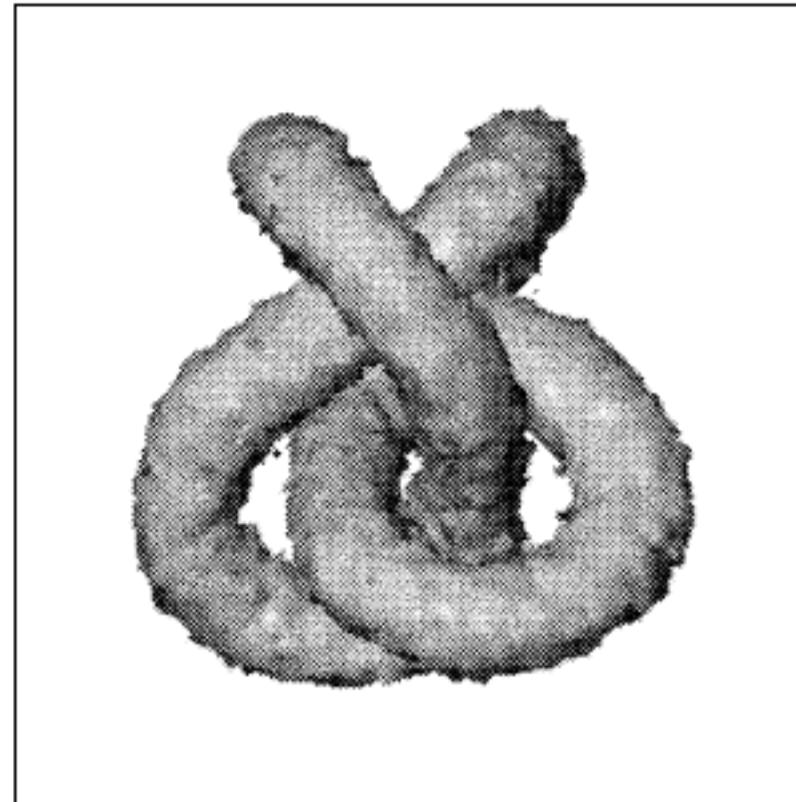

CAM-8: EM scattering

CAM-8: materials simulation

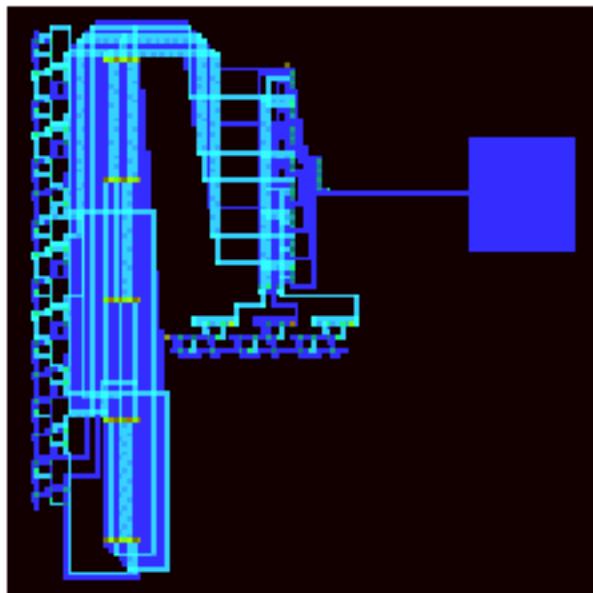

512x512x64 spin system, 6up/sec w rendering

256x256x256 reaction-diffusion (Kapral)

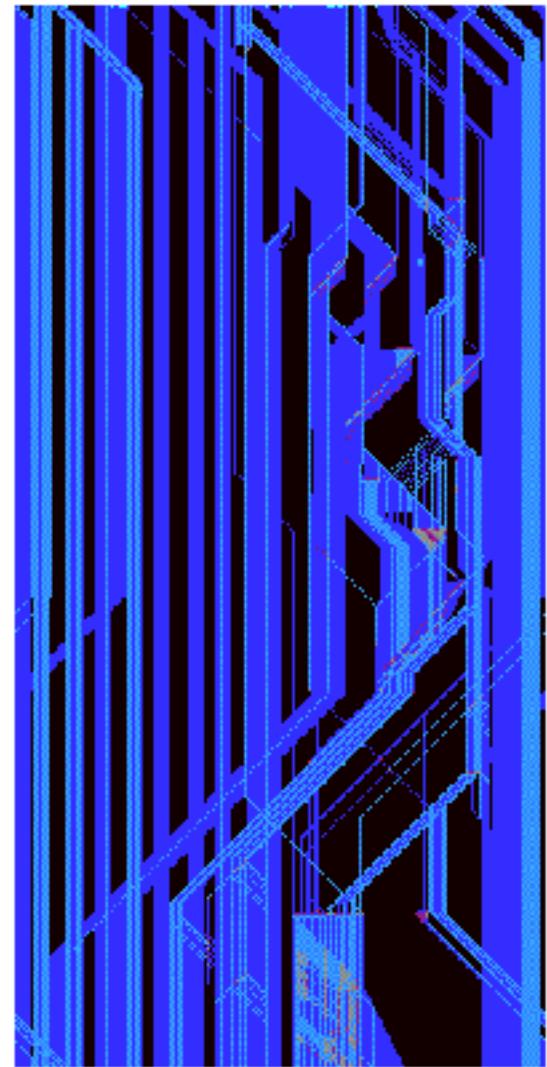

CAM-8: logic simulation

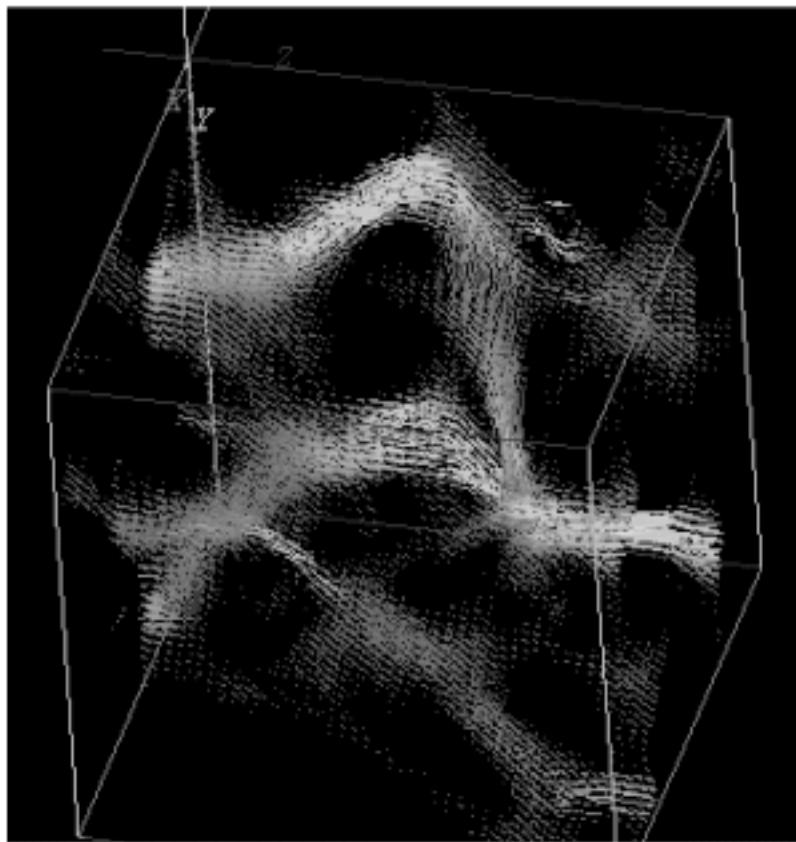

*A simple logic simulation in a
gate-array-like lattice dynamics.*

- Physical sim
- Logical sim
- Wavefront sim
- Microprocessor at right runs at 1KHz

*Wavefront
simulation
(R Agin)*

CAM-8: porous flow

64x64x64 simulation (.5mm/side)

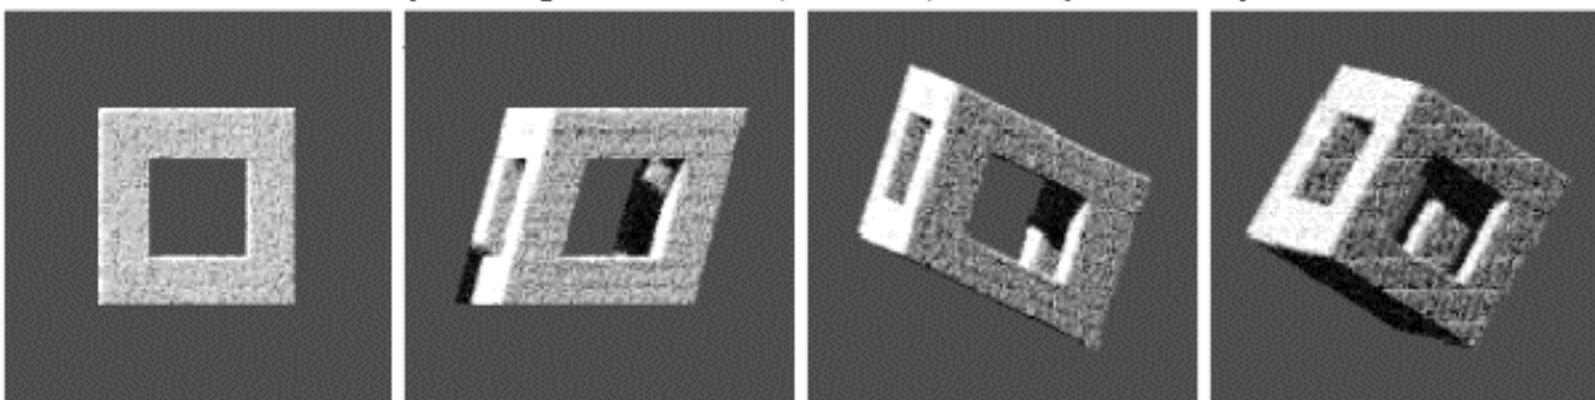

- Used MRI data from a rock (Fontainebleau sandstone)
- Simulation of flow of oil through wet sandstone agrees with experiment within 10%
- 3D LGA's used for chemical reactions, other complex fluids

CAM-8: image processing

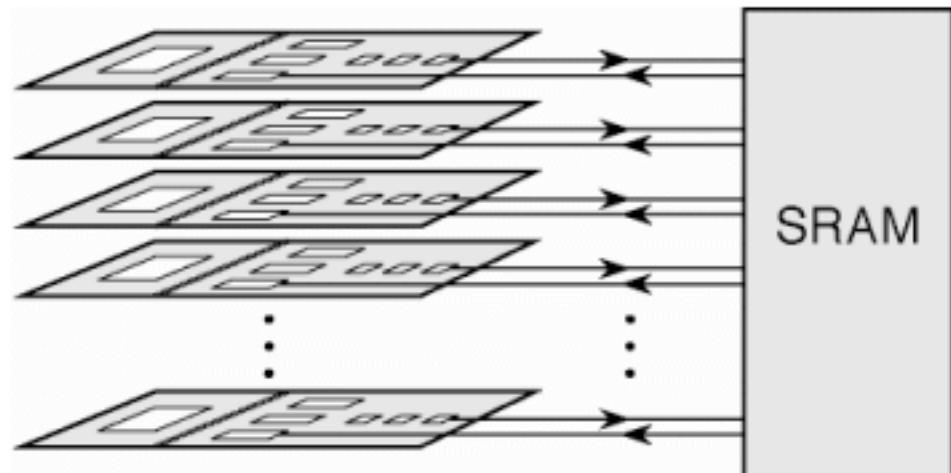

- Local dynamics can be used to find and mark features
- Bit maps can be “continuously” rotated using 3 shears

Three-dimensional rotation (Euler angles: $\alpha = -10^\circ$, $\beta = 30^\circ$, $\gamma = -15^\circ$) achieved by three shears.

CAM-8 node (1988 technology)

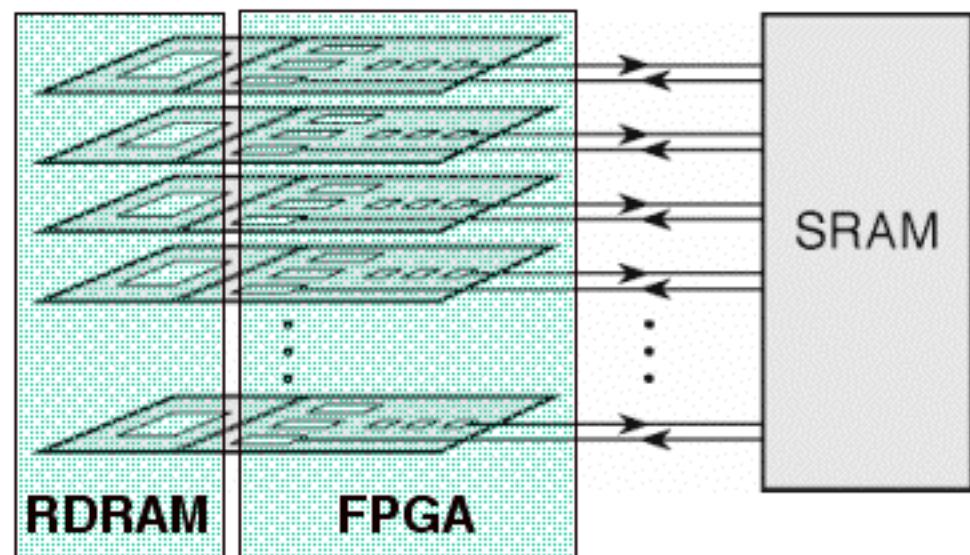

- 25 Million 16-bit site-updates/sec
- 8 node prototype
- arbitrary shifts of all bit fields at no extra cost
- limited by mem bandwidth
- still 100x PC!

**6MB/sec x
16 DRAMs
+ 16 ASICs** **25 MHz
64Kx16**

FPGA node design (1997)

- 100 x faster per DRAM chip
- No custom hardware
- Needed FPGA interface to RDRAM

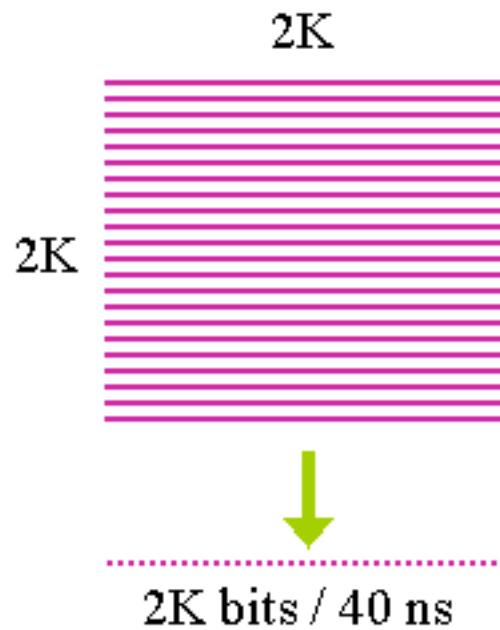

**600MB/sec
1 RDRAM
+ 1 FPGA**

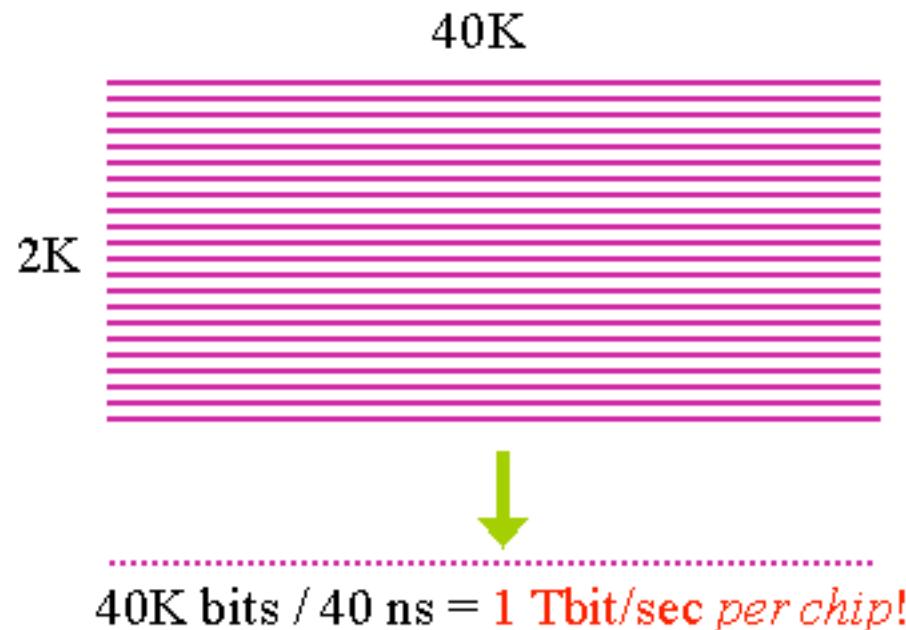

**150 MHz
64Kx16
pipelined**

Embedded DRAM (2000)

*4 Mbit Block
of DRAM:*

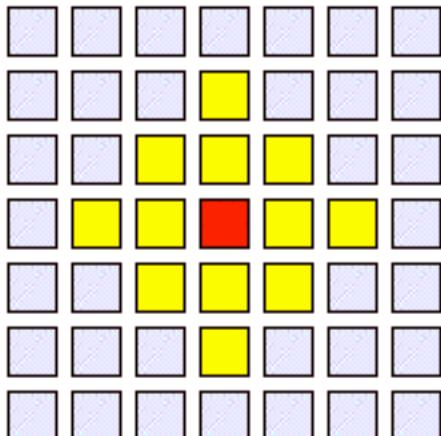

*20 Blocks of DRAM
(80 Mbits total):*

Each *chip* would be 1000x faster than 128-DRAM CAM-8!

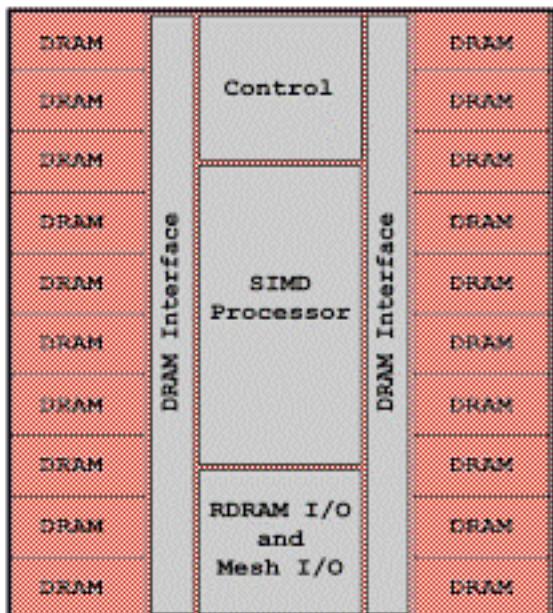

SPACERAM: A general purpose crystalline lattice computer

$$\begin{aligned}f_{x,y,t+1} = & \alpha f_{x+1,y,t} + \beta f_{x-1,y,t} + \gamma f_{x,y+1,t} \\& + \delta f_{x,y-1,t} + \varepsilon f_{x+1,y+1,t} + \zeta f_{x+1,y-1,t} \\& + \eta f_{x-1,y+1,t} + \iota f_{x-1,y-1,t} + \kappa f_{x+2,y,t} \\& + \mu f_{x-2,y,t} + \nu f_{x,y+2,t} + \sigma f_{x,y-2,t} \\& + \tau f_{x,y,t}\end{aligned}$$

- Large scale prob with spatial regularity
- 1 Tbit/sec $\approx 10^{10}$ 32-bit mult-accum / sec (sustained) for finite difference
- Many *image processing* and *rendering* algorithms have spatial regularity.
- Brute-force physical simulations (complex MD, fields, etc.)
- Bit-mapped 3D games and virtual reality (simpler and more direct)
- Logic simulation (physical, wavefront)
- Pyramid, multigrid and multiresolution computations

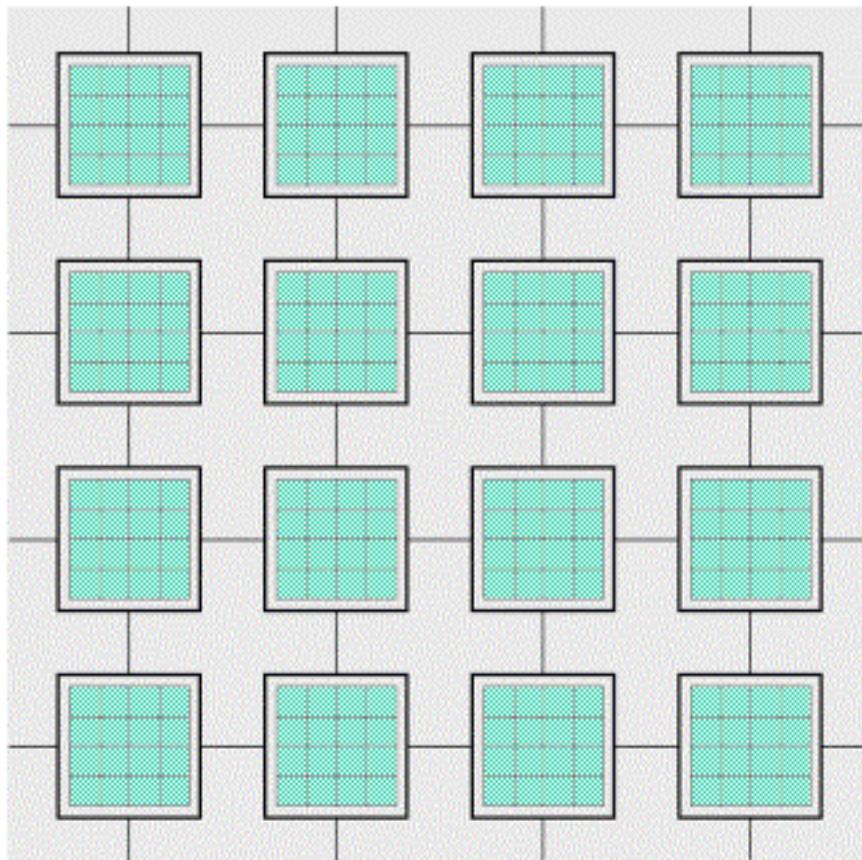

SPACERAM

4Mbits/DRAM, 256 bit I/O $\times 20$
@200 MHz \rightarrow 1 Tbit/sec, 10 MB,
130 mm² (.18 μ m) and 8 W (mem)

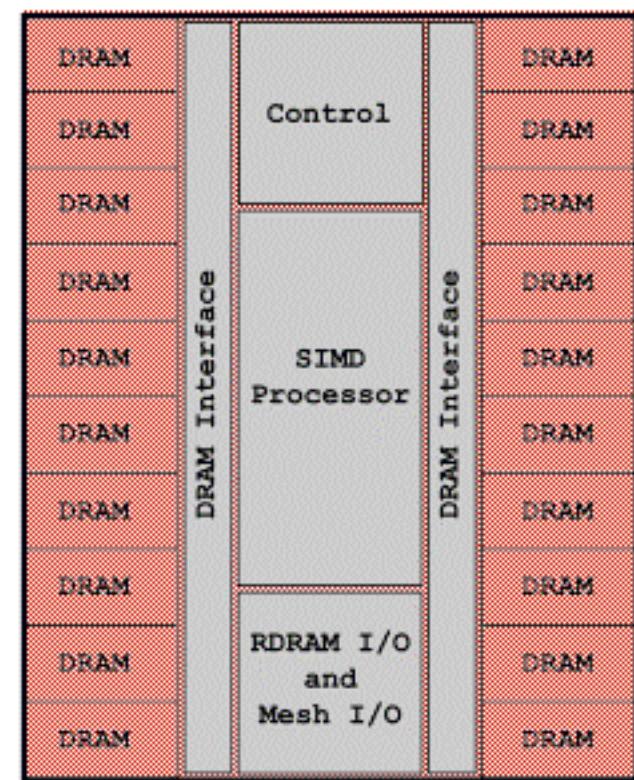

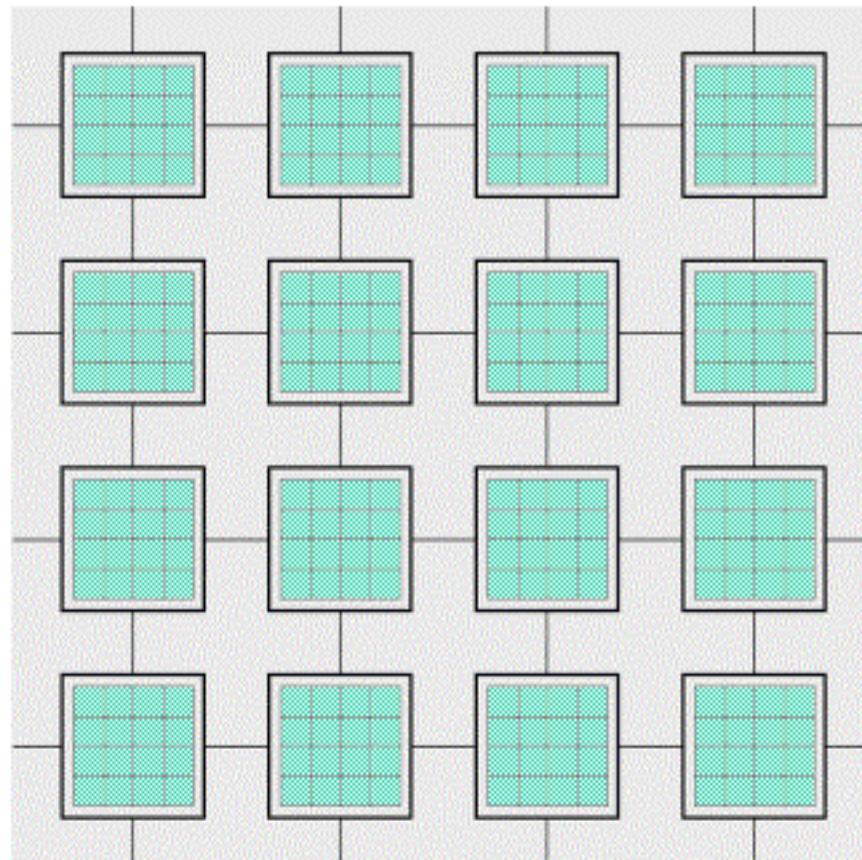

- *The Task:* Large-scale brute force computations with a crystalline-lattice structure
- *The Opportunity:* Exploit row-at-a-time access in DRAM to achieve speed *and* size.
- *The Challenge:* Dealing efficiently with memory granularity, commun, proc
- *The Trick:* Data movement by layout and addressing

Mapping a lattice into hardware

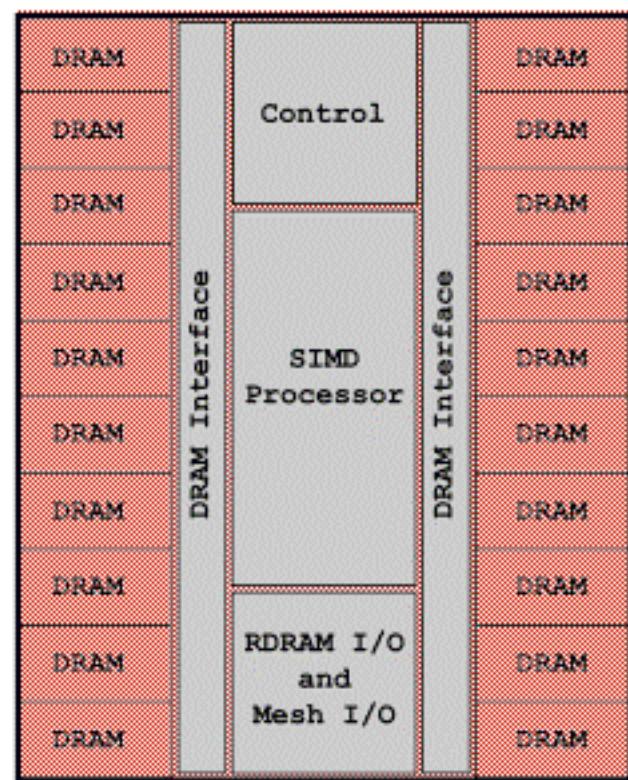

- Divide the lattice up evenly among mesh array of chips
- Each chip handles an equal sized *sector* of the emulated lattice

Mapping a lattice into hardware

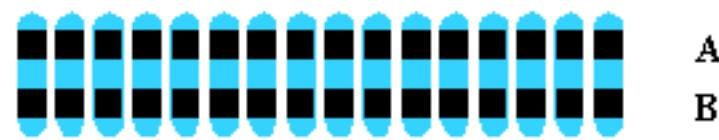

Mapping a lattice into hardware

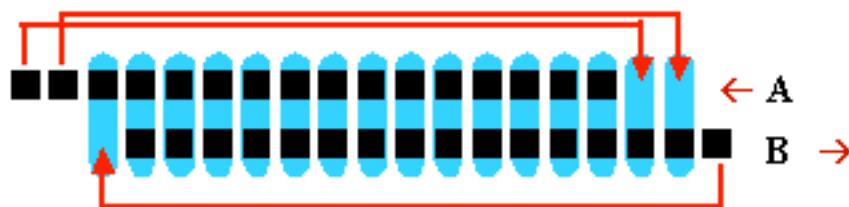

- Use blocks of DRAM to hold the lattice data (Tbits/sec)
- Use virtual processors for large comps (depth-first, waveform, skew)
- Main challenge: mapping lattice computations onto granular memory

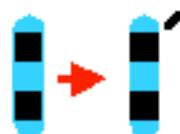

Lattice computation model

1D example: the rows are bit-fields and columns sites

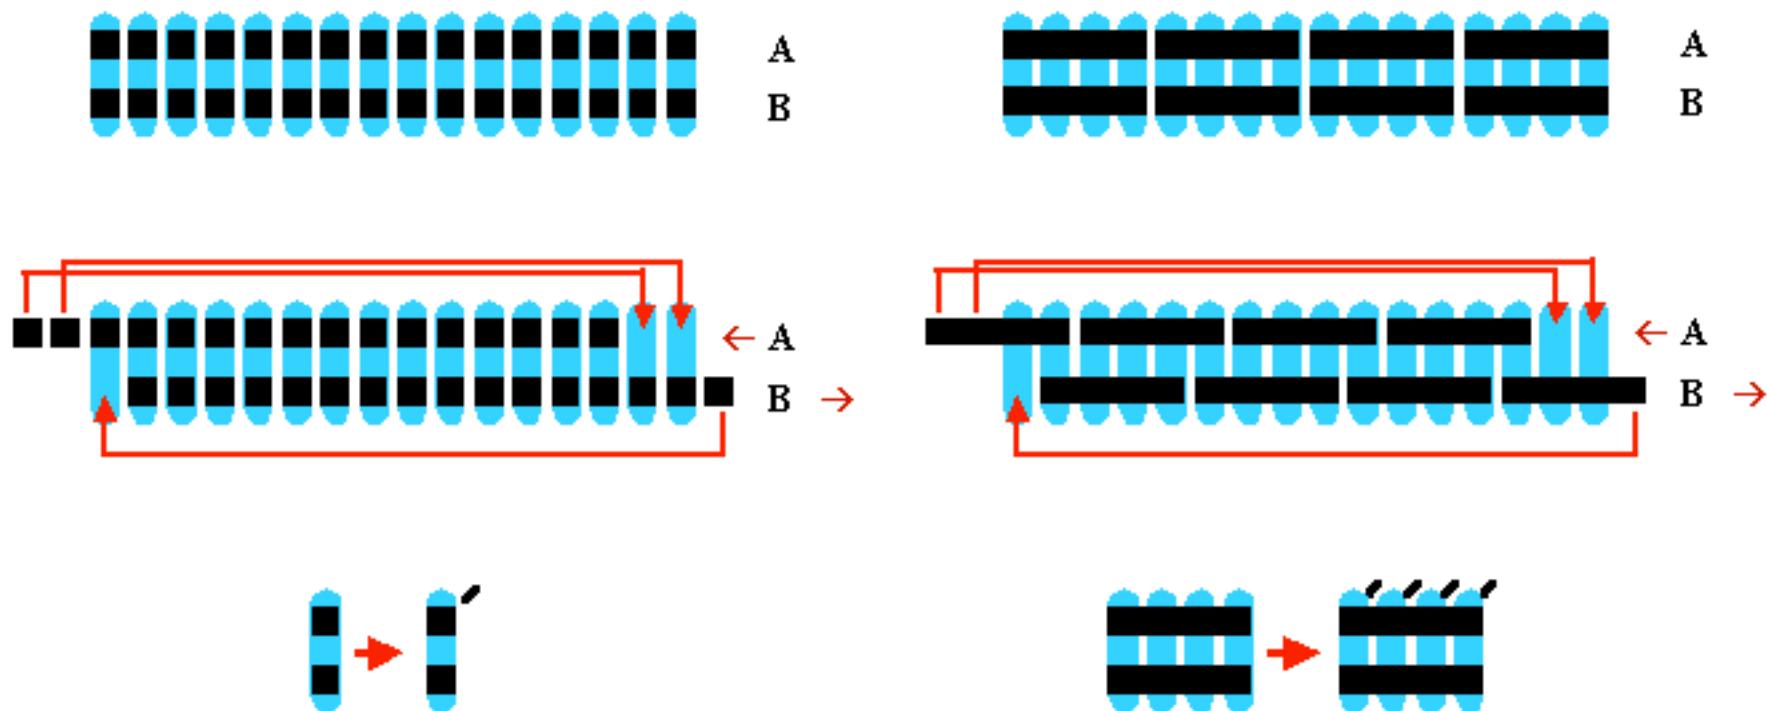

Shift bit-fields periodically and uniformly (may be large)

Process sites independently and identically (SIMD)

Mapping the lattice into memory

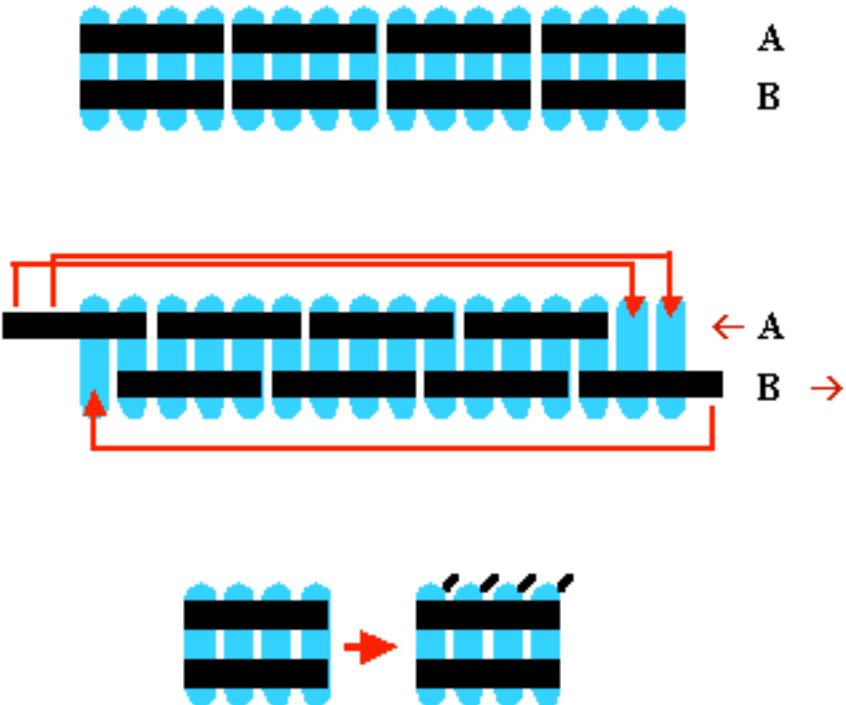

Mapping the lattice into memory

CAM-8 approach: group adjacent into memory words

Shifts can be long but re-aligning messy → chaining

*Can process word-wide
(CAM-8 did site-at-a-time)*

Mapping the lattice into memory

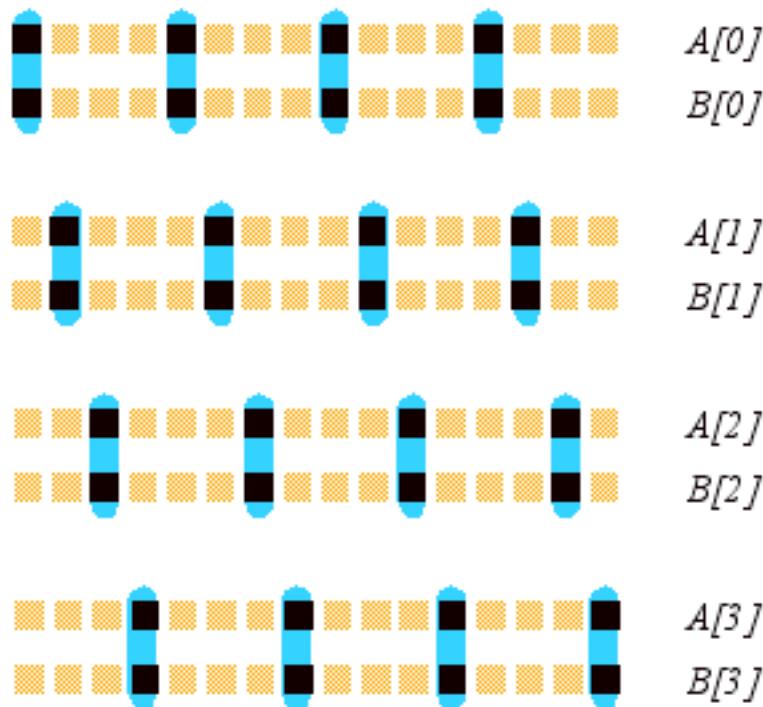

CAM-8: Adjacent bits of bit-field are stored together

Mapping the lattice into memory

$$\begin{array}{c} \blacksquare \\ + \\ + \\ + \end{array} = \begin{array}{c} \blacksquare \\ \blacksquare \\ \blacksquare \\ \blacksquare \end{array}$$

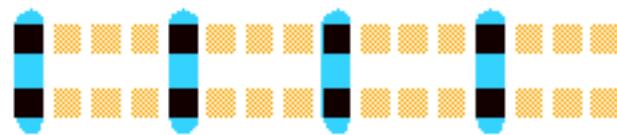

SPACERAM: bits stored as evenly spread skip samples.

Processing skip-samples

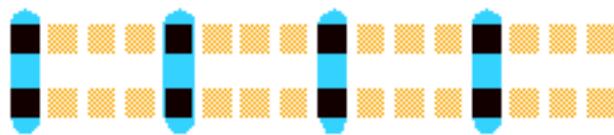

- Process sets of evenly spaced lattice sites (*site groups*)
- Data movement is done by reading shifted data

DRAM module

- Assume hardware word size is 64-bits
- Assume we can address any word
- For each site group: address next word we need; rot if necessary
- Each bit field resides in a different module

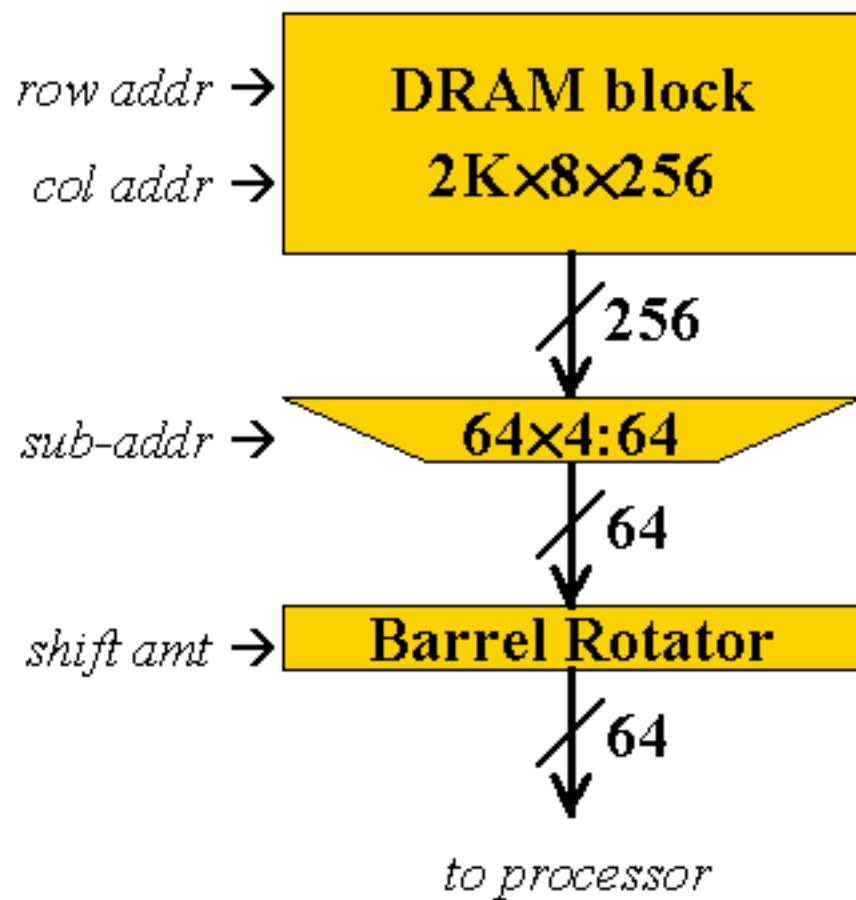

Problem: granularity

- DRAM block has structure: eg., all words in a row must be used before switching rows

Solution: grouping

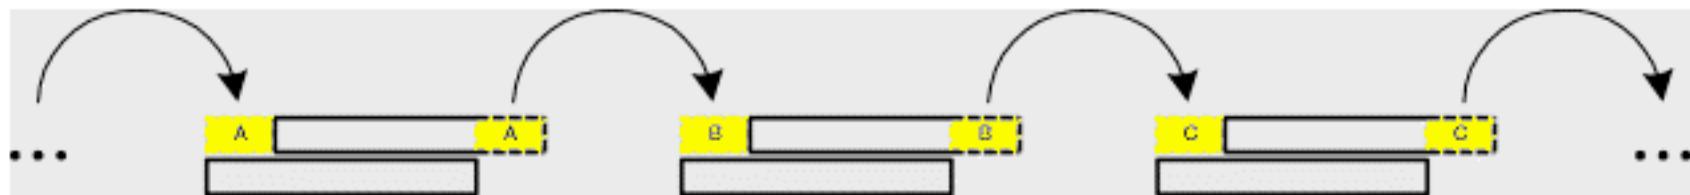

$$\text{[row of words]} = (\text{ [row of words] } + \text{ [row of words] }) \\ + (\text{ [row of words] } + \text{ [row of words] })$$

DRAM module

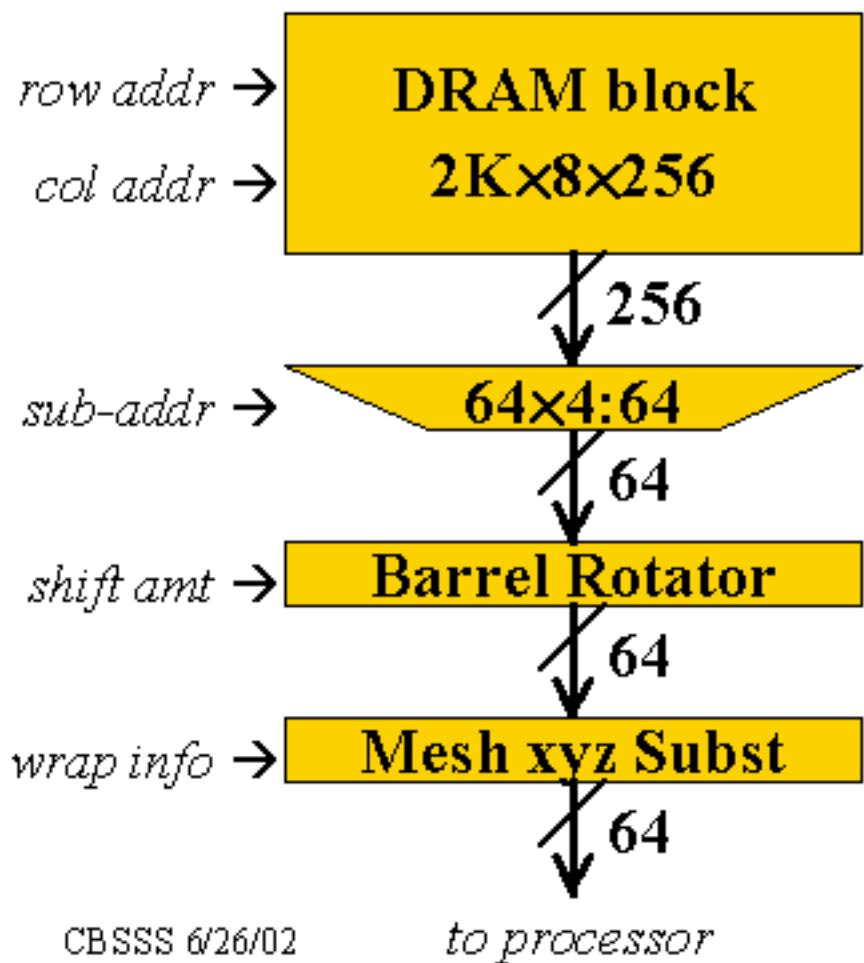

- 3 levels of granularity: 2K-bit row, 256-bit word, 64-bit word
- All handled by data layout, addressing, and rot within 64-word

Gluing chips together

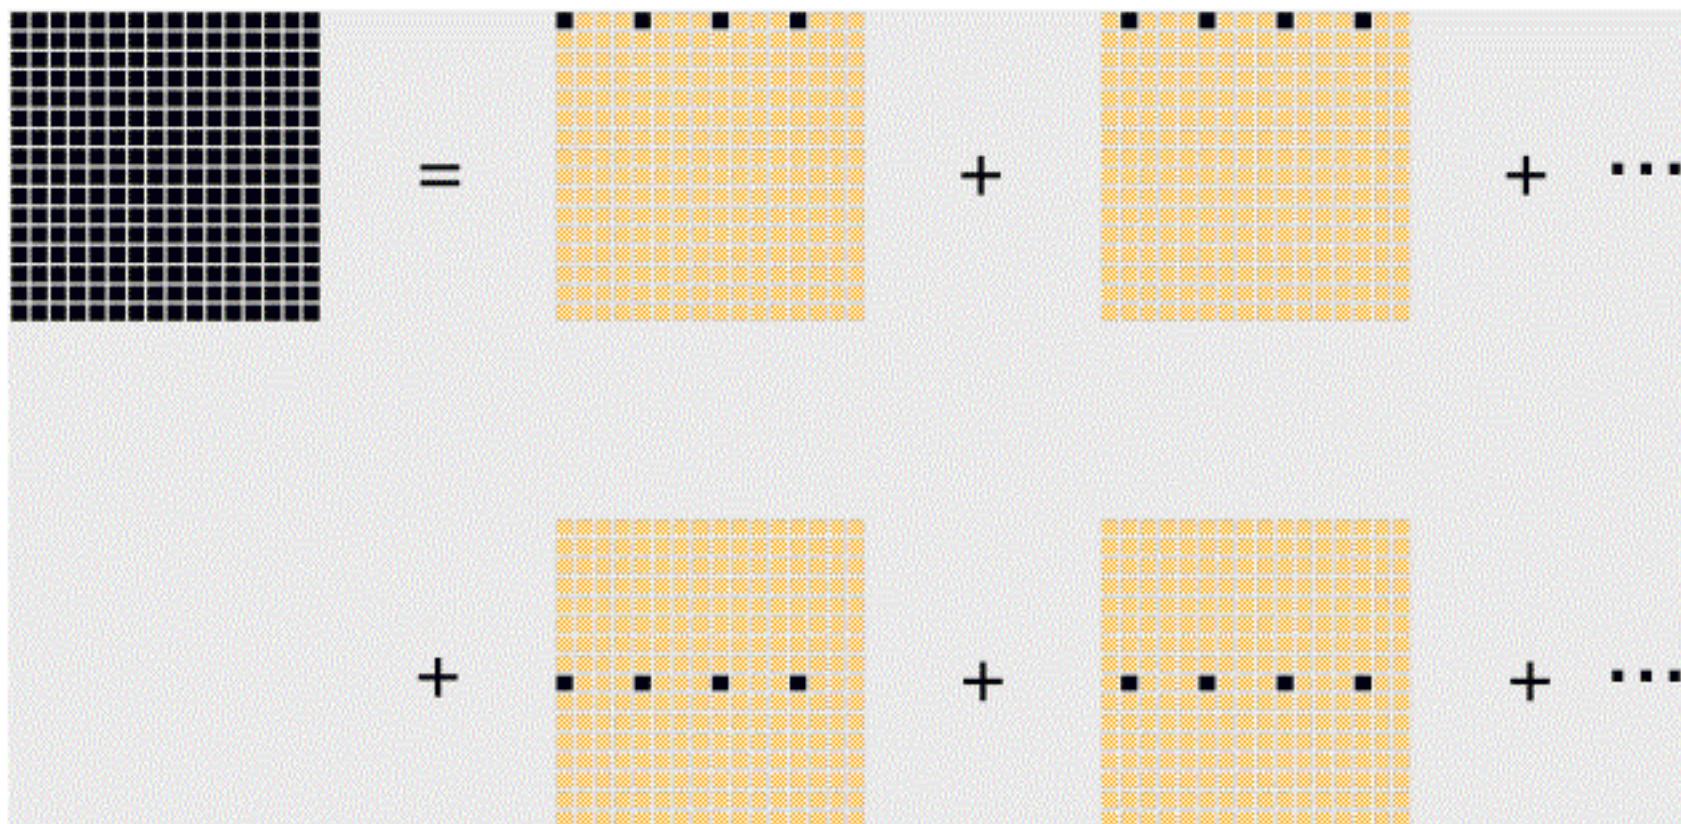

- All chips operate in lockstep
- Shift is periodic within each sector
- To glue sectors, bits that stick out replace corresponding bits in the next sector

DRAM module

- Any data that wraps around is transmitted over the mesh
- Corresponding bit on corresponding wire is substituted for it
- This is done sequentially in each of the three directions

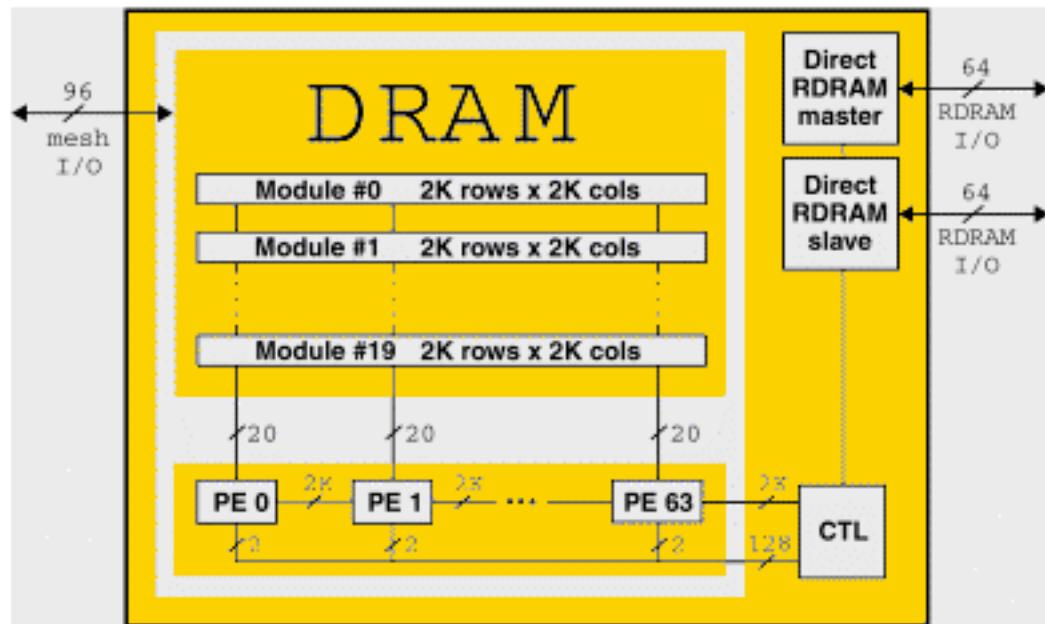

Partitioning a 2D sector

Partitioning a 2D sector

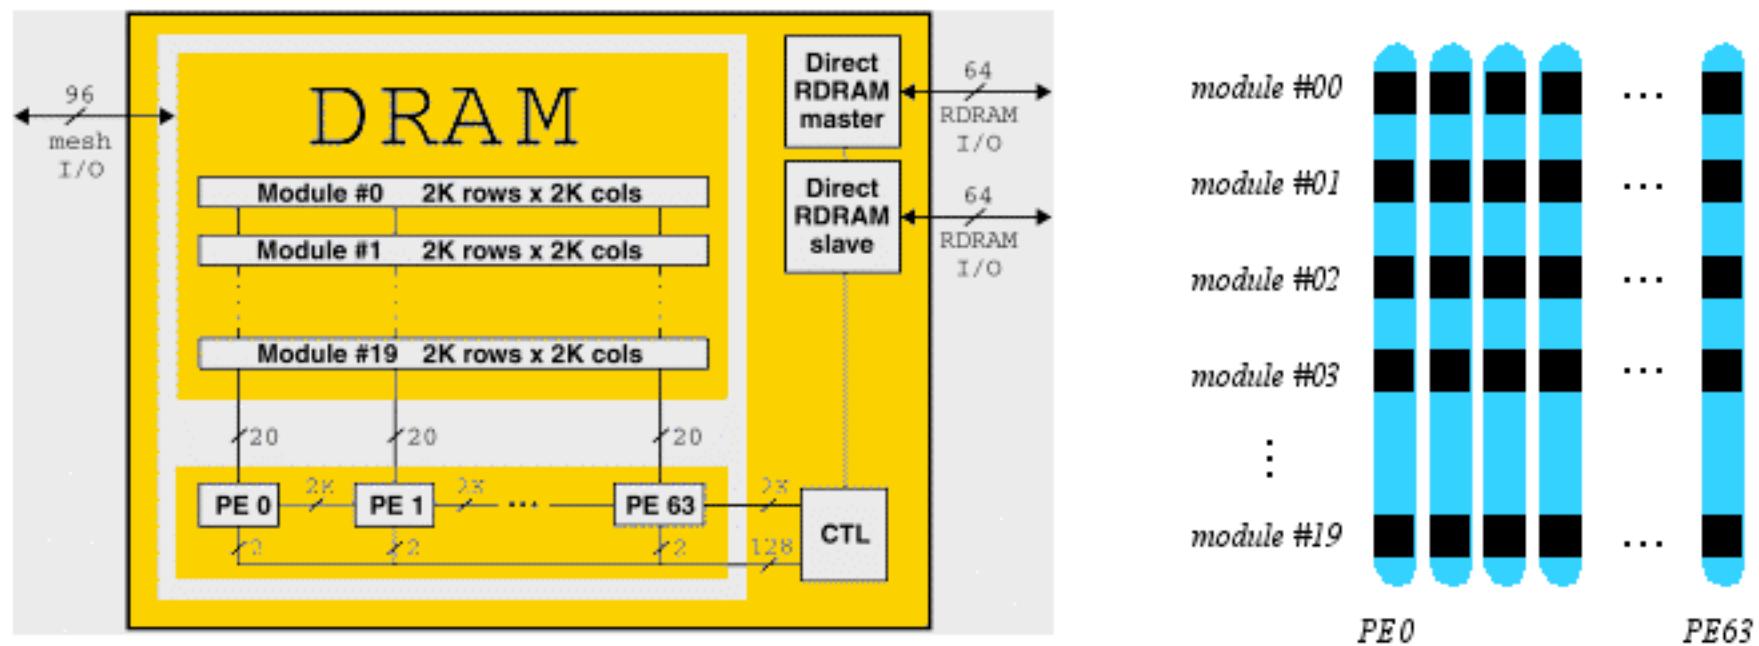

$$\begin{matrix} \text{A black square grid} \\ = \\ \text{A yellow square grid with black dots at } (1,1), (2,2), (3,3) \\ + \\ \text{A yellow square grid with black dots at } (1,1), (2,3), (3,2) \\ + \dots \\ + \\ \text{A yellow square grid with black dots at } (1,2), (2,1), (3,3) \\ + \\ \text{A yellow square grid with black dots at } (1,3), (2,2), (3,1) \\ + \dots \end{matrix}$$

The SPACERAM chip

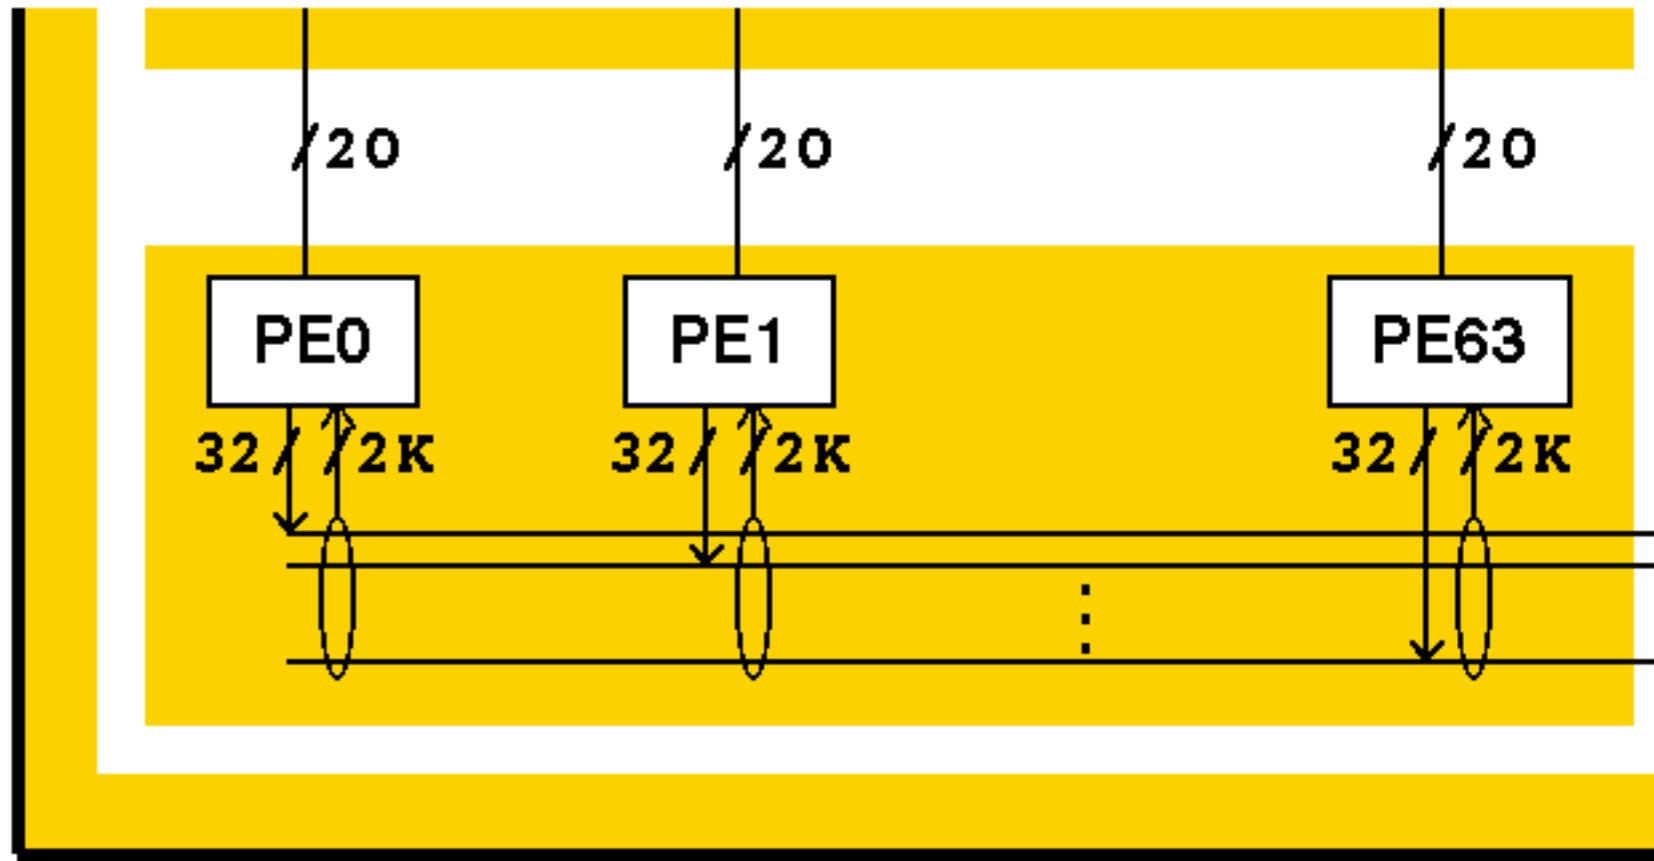

- .18 μ m CMOS DRAM proc. (20W, 215 mm²)
- 10% of memory bandwidth \rightarrow control
- Memory hierarchy (external memory)
- Single DRAM address space

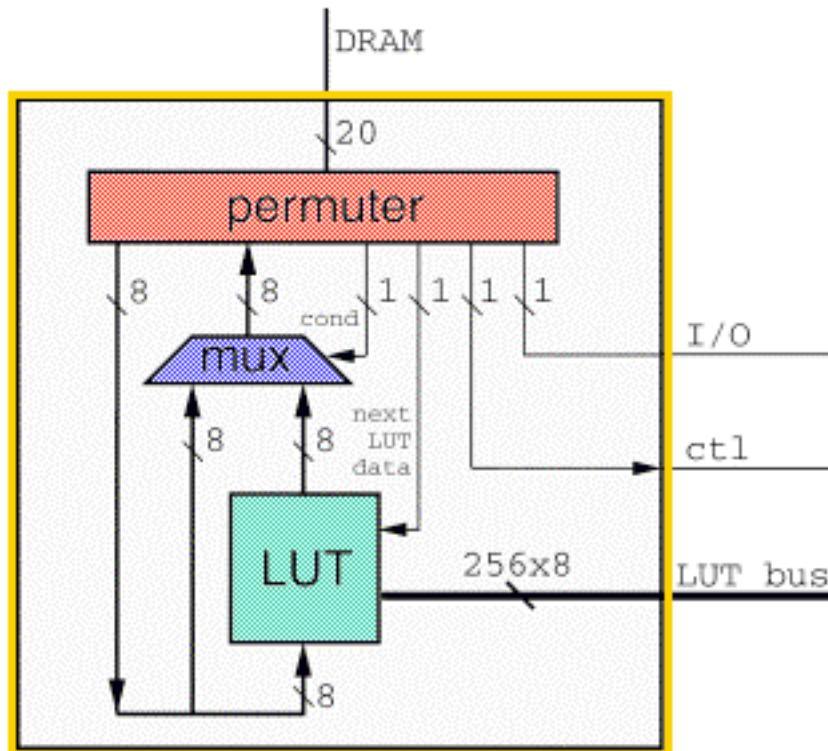

The SPACERAM chip

The SPACERAM chip

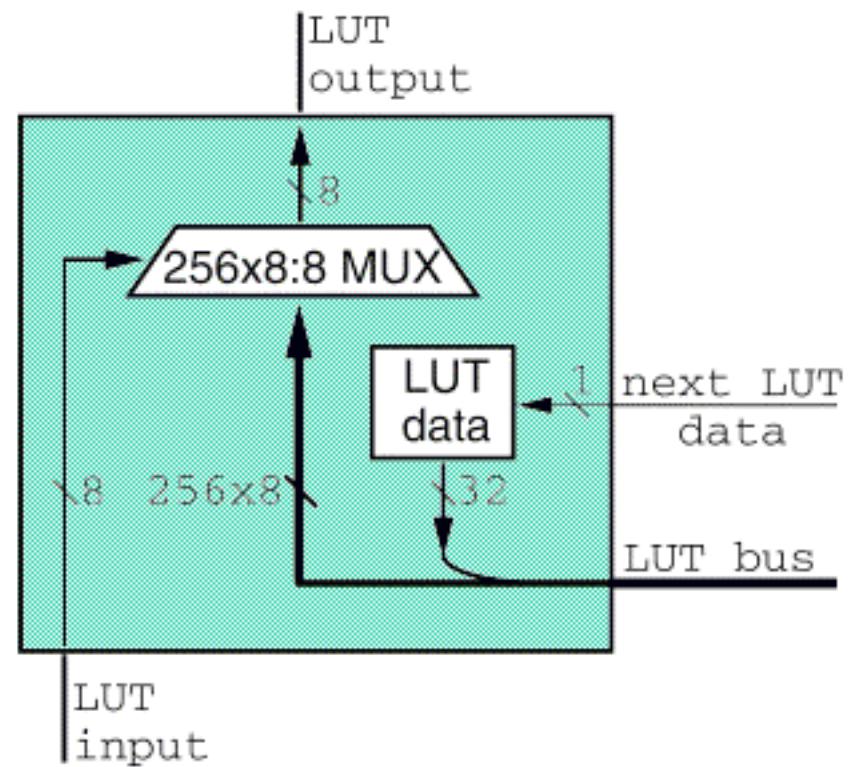

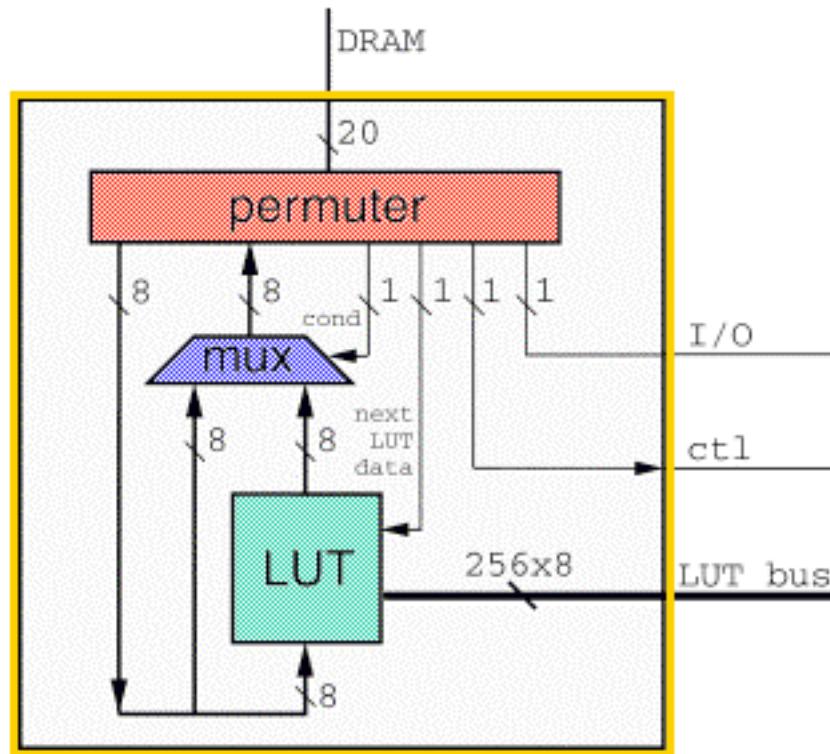

SPACERAM: symbolic PE

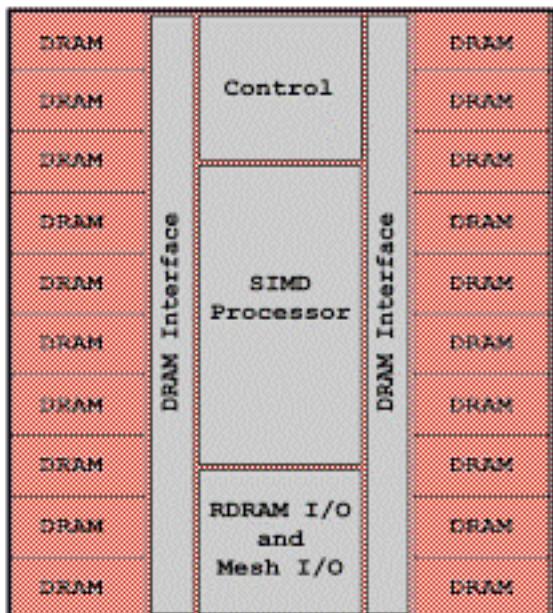

- Computation by LUT
- Permuter lets any DRAM wire play any role
- MUX lets LUT output be used conditionally
- LUT is really a MUX, with data bussed

SPACERAM: symbolic PE

Conclusions

. 18 μ m CMOS, 10 Mbytes DRAM,
1 Tbit/sec to mem, 215 mm², 20W

- Addressing is powerful
- Simple hardware provides a general mechanism for lattice data movement
- We can exploit the parallelism of DRAM access without extra overhead
