<u>Identification</u>

Current Ring Number Routine: get_ring_no
M. A. Padlipsky

Purpose

It is frequently necessary for a procedure to determine the number of the ring in which it is currently operating. The condition-handling mechanism (BD.9.04) in particular needs such information. Procedure get_ring_no is furnished by the protection mechanism to satisfy this need.

<u>Usage</u>

The calling sequence is

call get_ring_no (n);

with argument declared

dcl n fixed bin (17);

On return from get_ring_no, n will contain the ring number of the procedure which called get_ring_no.

Method

Get_ring_no is a ring O procedure. When called, it investigates the Stack frame immediately preceding its own: if that frame is a ring-crossing frame (see BD.9.01), the ring number of the caller is copied from the top entry on the Gatekeeper's $\langle \text{rtn_stk} \rangle$ into \underline{n} and $\underline{\text{get_ring_no}}$ returns; if the preceding frame is not a ring-crossing one, \underline{n} is set to zero and $\underline{\text{get_ring_no}}$ returns.
