Identification

Find a Path Name for a Call Name
search_for
S. L. Rosenbaum

Purpose

The function search_for answers the question: "Where
in the file system hierarchy would the Search Module (using
the current search rules) find a segment for a given call
name?" Search_for can be used to check out searching
rules and as an immediate-value command.

Usage

        path_name = search_for (call_name);

        dcl (search_for external entry, call_name, path_name)
            char (*) varying;

(Note: call_name may be declared either char(*) varying
or char (*).)

Implementation

The function search_for invokes the Search Module to find
a path name for the call name call_name. search_for returns
the path name as a varying character string; if no path
name was found, search_for returns a zero length character
string.
