# Rethinking Wireless Broadband Platforms

Focus: mass-market access networks

Wired networks are evolving to  
a broadband platform

Wireless networks will follow a  
different path

Story of wired network evolution

*From silos to platforms*

How wireless is different

*Silo architecture embedded*

Reasons & why this matters

How will wireless evolve?

*Hybrid wireless future*

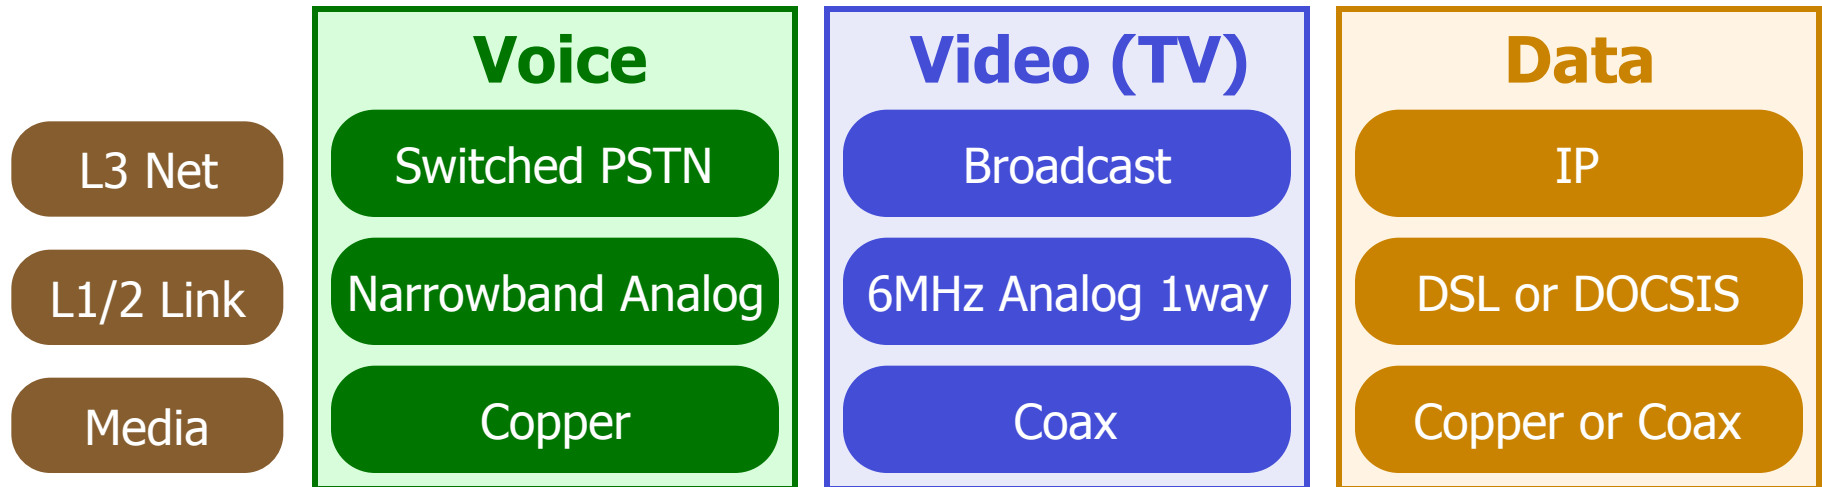

mediabistro

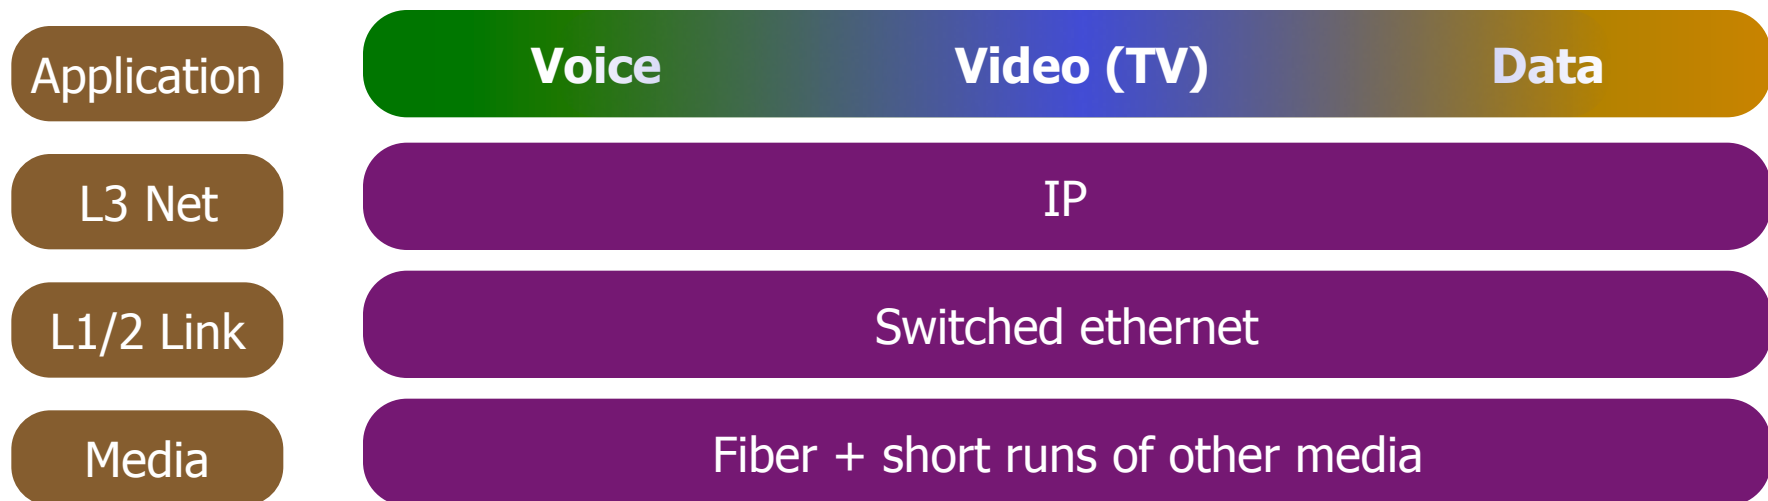

comenco

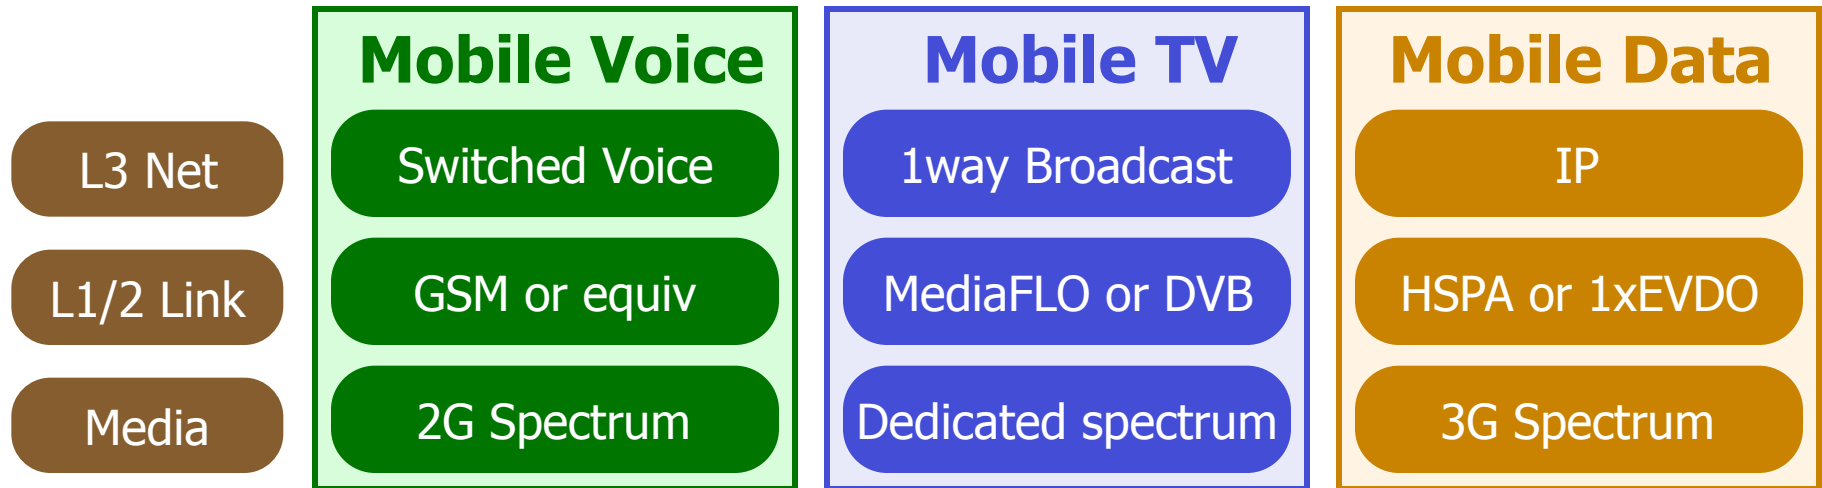

# Wired networks: silos to broadband platforms

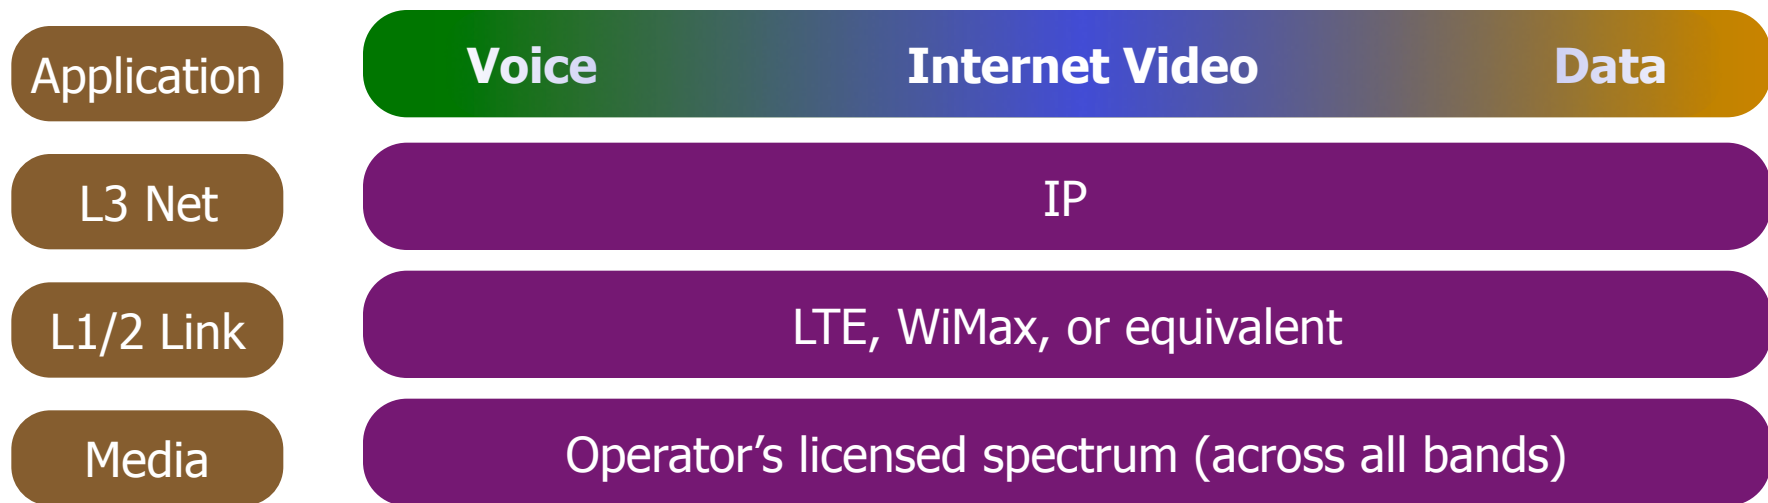

**Single-purpose, separate networks → Multi-purpose, integrated network**

# Wireless platform vision: same as wired

**Triple play bundle, separate networks → LTE or other 4G integrated network**

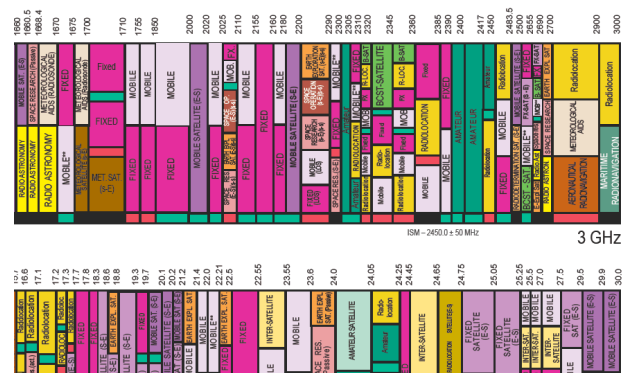

# 4G will not evolve as envisioned

Essential differences between wired and wireless mean that wireless nets unlikely to become integrated platforms

	<u>Wired</u>	<u>Wireless</u>
Capacity	Abundant	Scarce
Topology	Point-to-point	Broadcast
Reliability	Reliable	Unreliable
Mobility	Fixed	Mobile
Layering	Effective	Inefficient

*Scarcity of RF spectrum is the key difference.*

# Future of wireless broadband: Hybrid Networks

Application	Voice	TV	Voice	Video	Data
L3 Net	Switched Voice	1way Broadcast	IP		
L1/2 Link	New Air Interface	MediaFLO, DVB	LTE, WiMax, etc		
Media	Operator's licensed spectrum + shared spectrum (DSA, unlicensed)				

## Novel aspects of this model

Specialized air interfaces + dynamic reallocation of spectrum

Software radio supports all air interfaces with one radio

Overload on specialized net carried transparently by IP net

Operators exploit mix of dedicated and shared spectrum

End-user device plays active role in network selection

# Market implications of the essential differences

## Wired Broadband

1-2 (or a few) vertically-integrated similar platforms  
Network-centric, operator driven  
Over-the-top competition is key  
(open access to broadband Internet)

## Wireless Broadband

Many heterogeneous specialized platforms  
End users play larger role  
Low entry barriers are key  
(especially spectrum access)

Wired and wireless compete and complement  
Multiple equilibria are possible

- (1) Wireless bundle competition slows wired innovation
- (2) Wireless/wired bundles emphasize differentiation

Microsoft, LG, YesDigital

# Regulatory implications of the essential differences

## Interconnection & universal service

Separate regimes for wired and wireless

## Technical & service neutrality across wired & wireless

Not realistic

## Open Access

Wired: unbundle over-the-top

Wireless: spectrum

## Spectrum Policy

Enable Dynamic Spectrum

Access

## Key takeaway points

Wired and wireless broadband are fundamentally different

Wireless will not evolve towards broadband platforms

Future is a hybrid network with extensive spectrum sharing

Market structure will remain different

Even though the two broadband services compete with each other

Appropriate regulatory treatment will remain different

Detailed analysis of the hybrid network model and its implications will appear in a companion paper

Thank you for your attention!

# Definition of “Broadband Platform”

An integrated, high-capacity, general-purpose network

*Integrated* services share common lower layer functionality & resources

*High-capacity* capable of supporting triple play

*General-purpose* multiple and extensible set of services (traffic types)

*Network* access network including L1/2 (facilities based provider)
