Poll

Situation

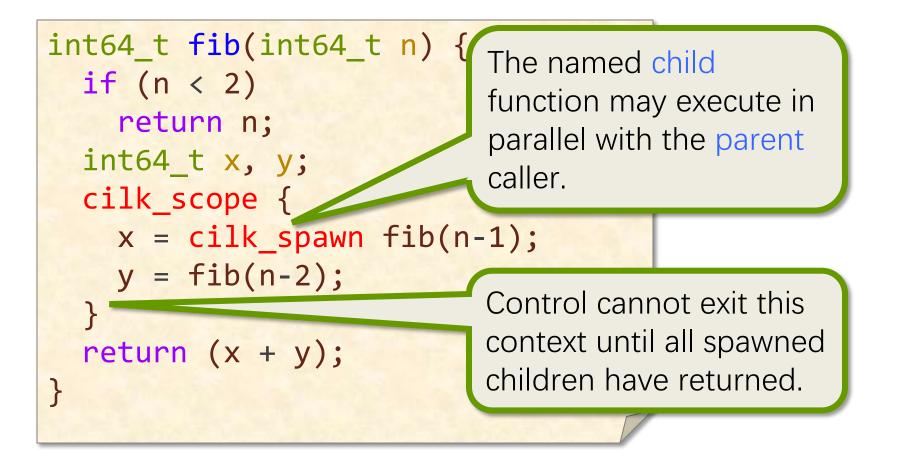

You and your partner discover a clever algorithm, compiler switch, etc. that speeds up your code.

- **Q**. Which of the following would you do?
 - a. Keep it secret so that you can beat the other teams.
 - b. Publish the idea on Piazza.

Course Policy

- 1. You are not competing with other teams. The cutoffs for grades are determined independently of how teams perform.
- 2. You receive class-contribution points for sharing ideas and code snippets on Piazza.
- 3. You may not copy code, but you can take inspiration from each other.

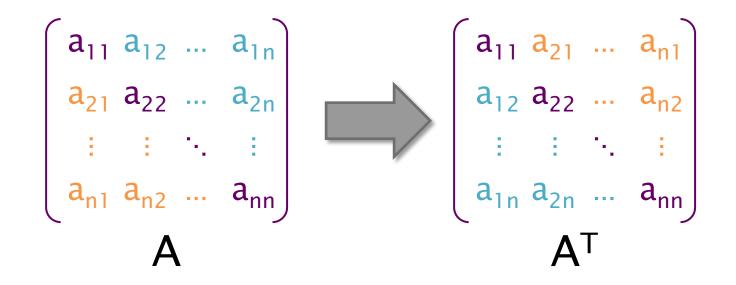

Nested Parallelism in Cilk

Cilk keywords grant permission for parallel execution. They do not command parallel execution.

Loop Parallelism in Cilk

Example: In-place matrix transpose

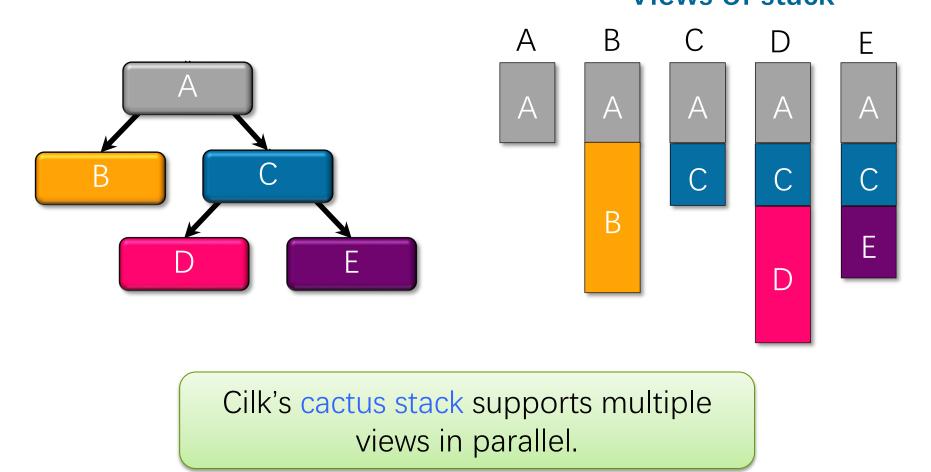

The iterations of a cilk_for loop execute in parallel.

// indices run from 0, not 1 cilk_for (int i=1; i<n; ++i) {</pre> for (int j=0; j<i; ++j) {</pre> double temp = A[i][j]; A[i][j] = A[j][i];A[j][i] = temp;

Cactus Stack

Cilk supports C's rule for pointers: A pointer to stack-allocated memory can be passed from parent to child, but not from child to parent.

DETERMINACY RACES

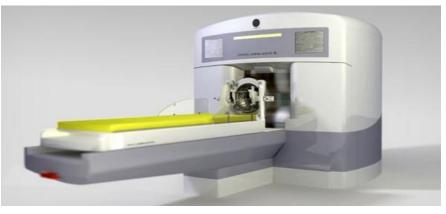

© 2008–2022 by the MIT 6.106/6.172 Lecturers

Race Conditions

Race conditions are the bane of concurrency. Famous race bugs include the following:

- Therac-25 radiation therapy machine — killed 3 people and seriously injured many more.
- Northeast Blackout of 2003 left
 50 million people without power.

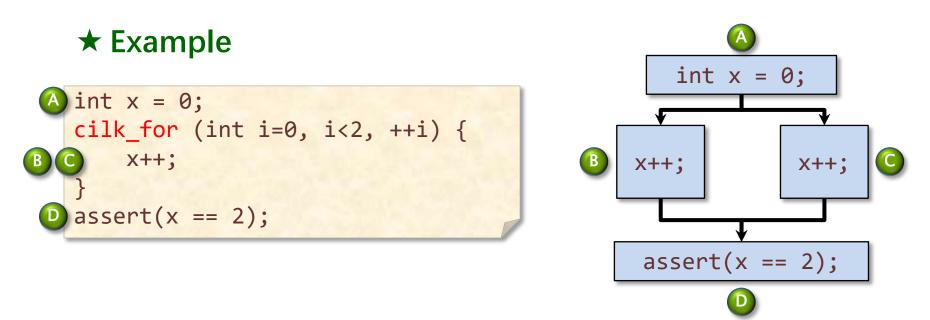

Race bugs are notoriously difficult to discover by conventional testing!

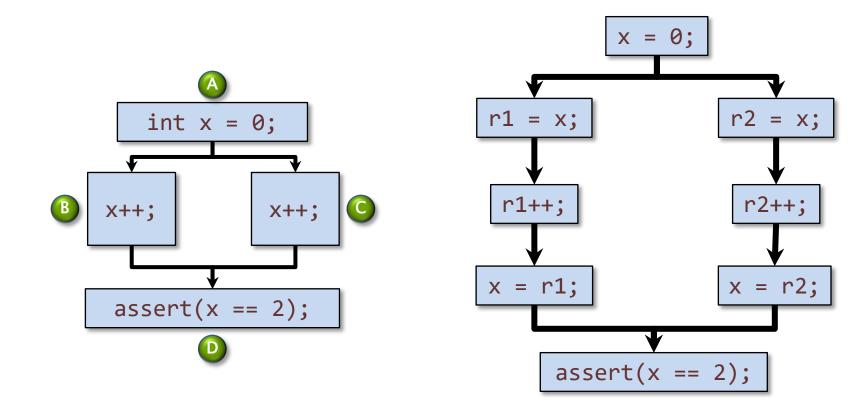

Determinacy Races

Definition. A determinacy race occurs when two logically parallel instructions access the same memory location and at least one of the instructions performs a write.

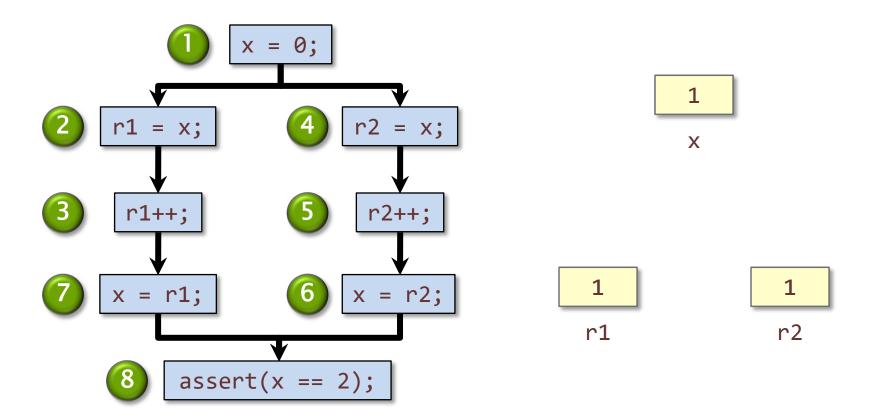

Trace

A Closer Look

Race Bugs

Definition. A determinacy race occurs when two logically parallel instructions access the same memory location and at least one of the instructions performs a write.

Types of Races

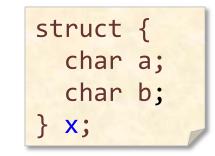

Suppose that instruction A and instruction B both access a location x, and suppose that $A/\!/B$ (A is parallel to B).

А	В	Race Type
read	read	none
read	write	read race
write	read	read race
write	write	write race

Two sections of code are independent if they have no determinacy races between them.

Avoiding Races

- Iterations of a **cilk_for** should be independent
- After a cilk_spawn, the code executed by the spawned task should be independent of the subsequent code executed by the parent and any tasks that the parent spawns or calls, until the cilk_scope block is exited
 - Note: The arguments to a spawned function are evaluated in the parent before the spawn occurs.
- Machine word size matters. Watch out for races in packed data structures:

Ex. Updating **x.a** and **x.b** in parallel may cause a race! Nasty, because it may depend on the compiler optimization level. (Safe on x86-64.)

Cilksan Race Detector

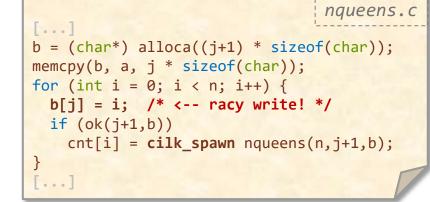

- Compile with the -fsanitize=cilk command-line compiler switch to produce a Cilksan-instrumented program which you run on program inputs.
- If an ostensibly deterministic Cilk program could possibly behave differently on a given input than its serial projection, Cilksan guarantees to report and localize the offending race.
- Cilksan employs a regression-test methodology, where the programmer provides test inputs.
- Cilksan identifies filenames, lines, and variables involved in races, including stack traces.
- Ensure that all program files are instrumented, or you'll misses ugs.
- Cilksan is your best friend.

Race Example: Queens

```
inqueens.c
inqueens.c
inqueens.c
inqueens.c
inqueens.c
inqueens.c
int i = (char*) alloca((j+1) * sizeof(char));
memcpy(b, a, j * sizeof(char));
for (int i = 0; i < n; i++) {
    b[j] = i; /* <-- racy write! */
    if (ok(j+1,b))
        cnt[i] = cilk_spawn nqueens(n,j+1,b);
}
[...]</pre>
```

OpenCilk Cilksan Execution

•The runtime overhead is nearly constant compared with a serial execution.

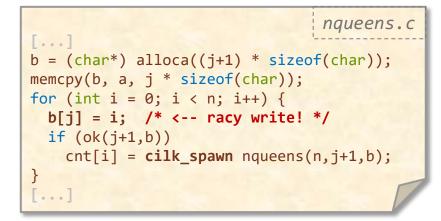

□ ~7× slower for this example.

Tips for Effective Performance Engineering

- Maintain the invariant that your code is correct.
- Regression test heavily and automatically to ensure correctness.
- Don't be a slob: Treat your source code with respect.

Good code hygiene enables fast code.

Trace Dag

- A parallel instruction stream (trace) is a dag G = (V, E).
- Each vertex $v \in V$ is a strand: a sequence of instructions not containing a spawn, sync, or return from a spawn.
- An edge $e \in E$ is a spawn, call, return, or continue edge.
- The compiler converts loop parallelism (cilk_for) to spawns and syncs using recursive divide-and-conquer.

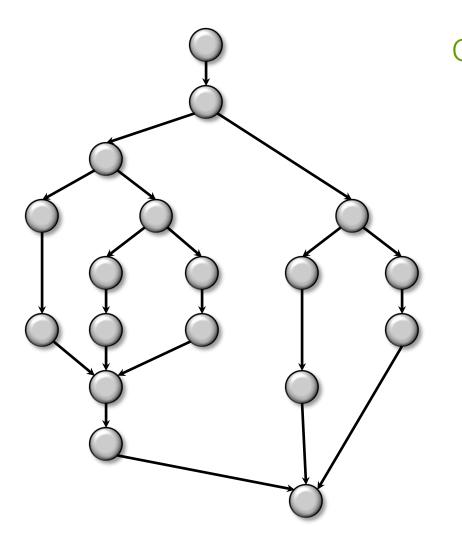

How Much Parallelism?

Assuming that each strand executes in unit time, what is the parallelism of this computation?

In other words, what is the maximum possible speedup of this computation, where speedup is how much faster the parallel code runs compared to the serial code?

Amdahl's "Law"

Gene M. Amdahl

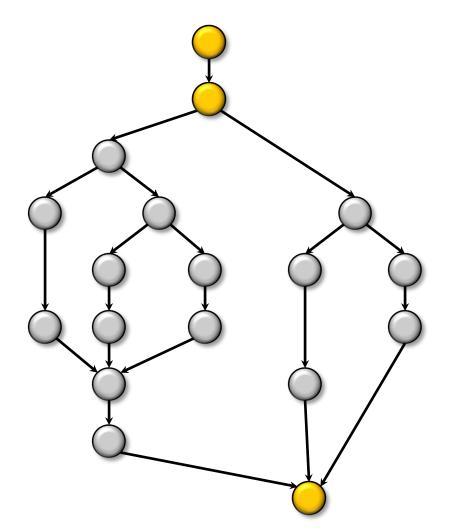

In general, if a fraction α of an application must be run serially, the speedup can be at most $1/\alpha$.

*Paraphrased.

Quantifying Parallelism

What is the parallelism of this computation?

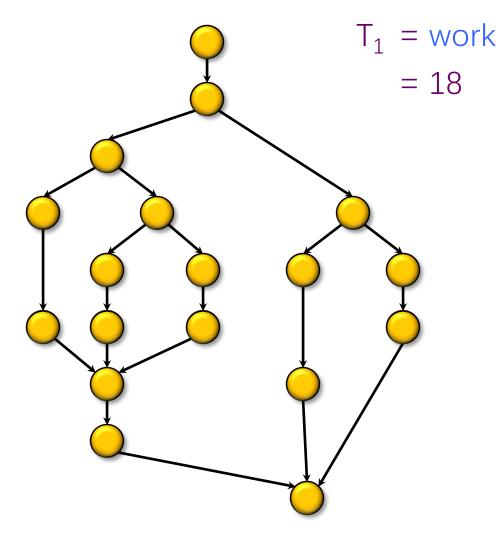

Amdahl's Law says that since the serial fraction is 3/18 = 1/6, the speedup is upper-bounded by 6.

But this bound is weak.

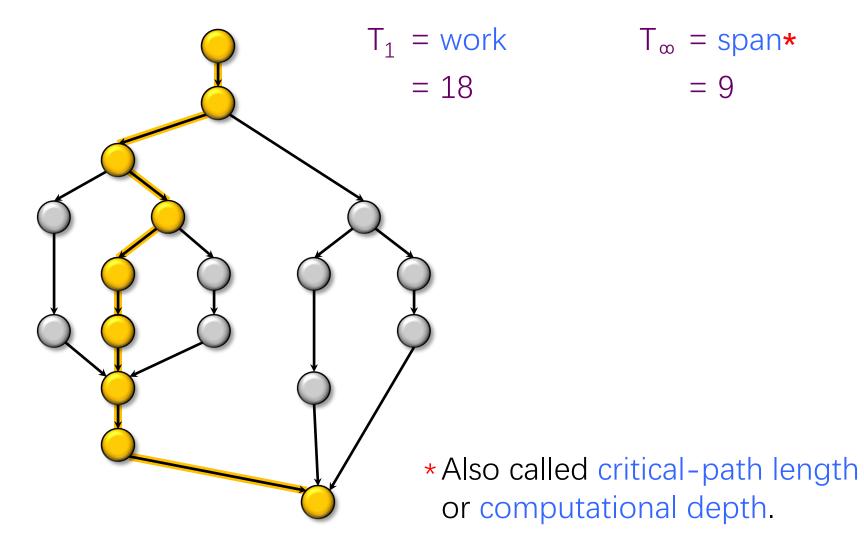

Performance Measures

Performance Measures

Performance Measures

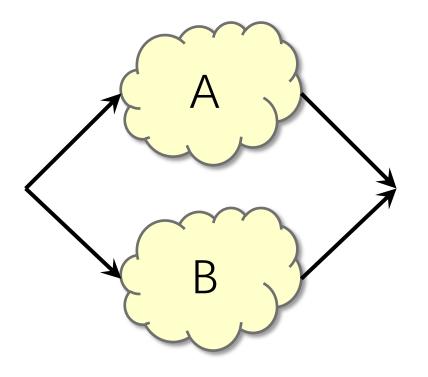

Series Composition

Work: $T_1(A \cup B) = T_1(A) + T_1(B)$ Span: $T_{\infty}(A \cup B) = T_{\infty}(A) + T_{\infty}(B)$

© 2008–2022 by the MIT 6.106/6.172 Lecturers

Parallel Composition

Work: $T_1(A \cup B) = T_1(A) + T_1(B)$ Span: $T_{\infty}(A \cup B) = \max\{T_{\infty}(A), T_{\infty}(B)\}$

Speedup

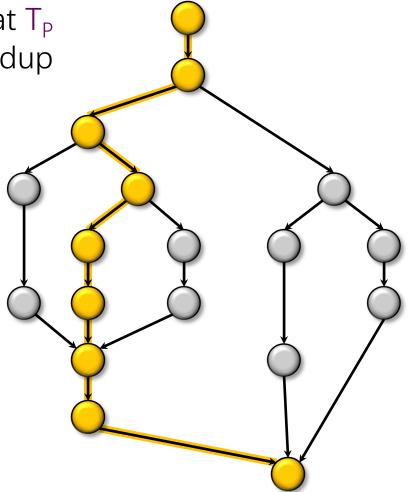

Definition. T_1/T_P = speedup on P processors.

- If $T_1/T_P = P$, we have (perfect) linear speedup.
- If T_1/T_P < P, we have sublinear speedup.
- If $T_1/T_P > P$, we have superlinear speedup, which is not possible in this simple performance model, because of the WORK LAW $T_P \ge T_1/P$.

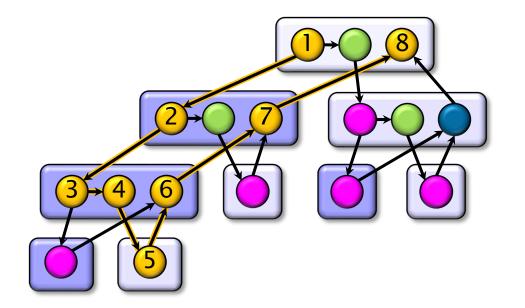

Parallelism

•Because the SPAN LAW dictates that $T_P \ge T_{\infty}$, the maximum possible speedup given T_1 and T_{∞} is

- • T_1/T_{∞} = parallelism
- the average amount of work per step along the span
- = 18/9
- = 2.

Example: fib(4)

Assume for simplicity that each strand in fib(4) takes unit time to execute.

Work: $T_1 = 17$ *Span:* $T_{\infty} = 8$ *Parallelism:* $T_1/T_{\infty} = 2.125$

Using many more than 2 processors can yield only marginal performance gains.

THE CILKSCALE SCALABILITY ANALYZER

SPEED LIMIT

PER ORDER OF 6.106

Cilkscale Scalability Analyzer

- The OpenCilk compiler provides a scalability analyzer called Cilkscale, which is similar in some ways to Intel's Cilkview tool.
- Like the Cilksan race detector, Cilkscale uses compiler instrumentation to analyze a serial execution of a program.
- Cilkscale computes work and span to derive upper bounds on parallel performance of all or just part of your program.
- Cilkscale is really three tools in one:
 - an analyzer,
 - an autobenchmarker,
 - a visualizer.

Parallelizing Quicksort

Example: Quicksort

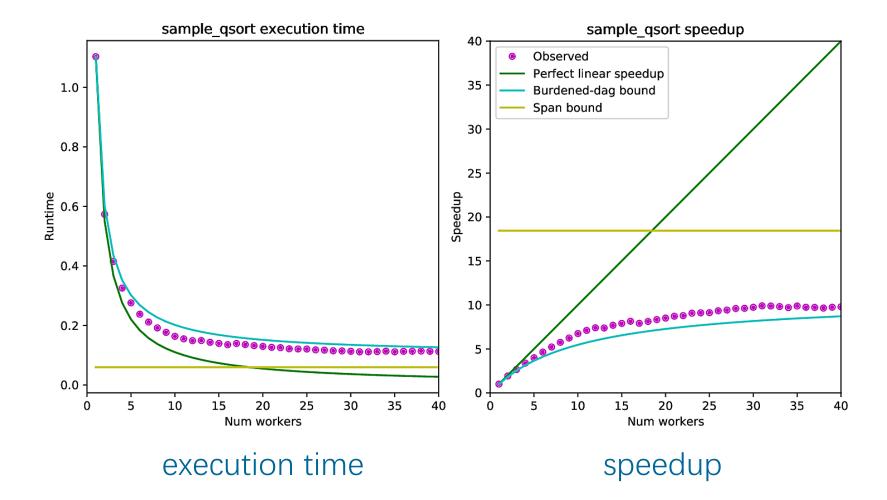

```
static void qsort(int * begin, int * end)
 if (begin < end) {</pre>
     int last = *(end - 1);
     // linear-time partition
     int * middle = partition(begin, end - 1, last);
     // move pivot to middle
     swap(end - 1, middle);
     // recurse
     qsort(begin, middle);
     qsort(middle + 1, end);
}
```

Parallelizing Quicksort

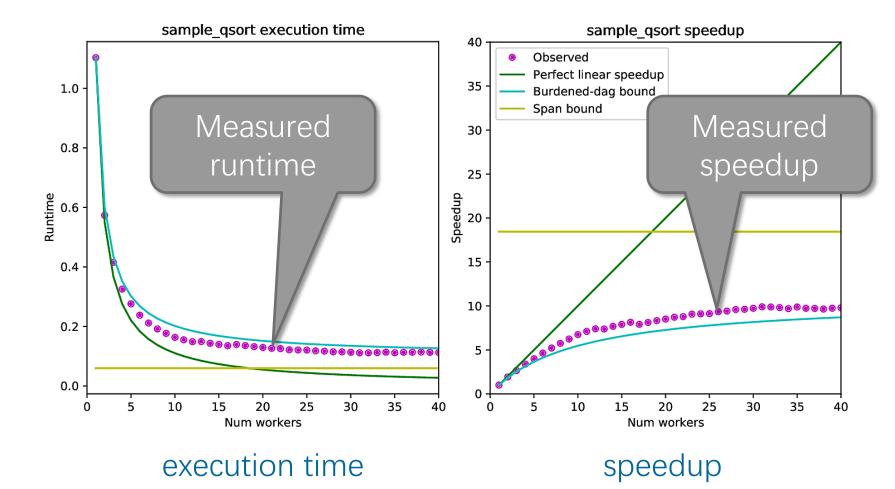

```
Example: Parallel quicksort
static void p qsort(int* begin, int* end)
  if (begin < end) {</pre>
      int last = *(end - 1);
     // linear-time partition
      int * middle = partition(begin, end - 1, last);
     // move pivot to middle
      swap(end - 1, middle);
     // recurse
      cilk scope {
        cilk_spawn p_qsort(begin, middle);
        p qsort(middle + 1, end);
```

Analyze the sorting of 10,000,000 numbers. *** *Guess the parallelism!* ***

Cilkscale: Scalability Visualizer

Cilkscale: Scalability Visualizer

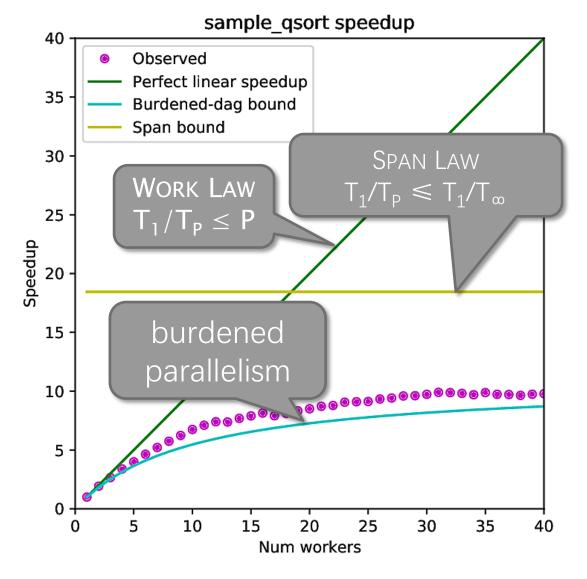

Cilksan autobenchmarks the code, running it on 1, 2, 3, ... processors, and the visualizer displays the results.

Cilkscale: Speedup Analysis

Cilkscale's analyzer determines the work and span, and the visualizer plots the WORK and SPAN LAWS.

 The visualizer also plots burdened parallelism, which indicates whether the program might incur scheduling overhead.

*Cilk on 1 processor competitive with the best C

- Determinacy races are usually bugs.
- Determinacy races can be detected and localized using Cilksan and a good regression-testing methodology.
- The WORK and SPAN LAWS provide lower bounds on the parallelism (maximum possible speedup).
- Cilkscale can analyze the work, span, and parallelism of a computation
- Many highly parallel and work-efficient algorithms can be programmed in Cilk.
