

# Outline

## First talk:

- Background on hash function
- Previous work on SHA-0, and SHA-1
- Improved collision search attack on SHA-0
  - Brief description

## Second talk:

- Collision search attack on SHA-1
  - Major steps, with focus on intuition
- Summary

# Efficient Collision Search Attacks on SHA-0

CRYPTO 2005  
August 15, 2005

Xiaoyun Wang  
Hongbo Yu  
Yiqun Lisa Yin

# Hash functions

- *Cryptographic* hash function:  $y = h(x)$ 
  - Take a message  $x$  of arbitrary length
  - Output a short value  $y$  of a fixed length
    - $y$  is called *hash value* or *message digest*
- Basic security properties
  - **One-way**: given  $y$ , hard to find  $x$  s.t.  $x = h^{-1}(y)$
  - **Collision resistant**: hard to find  $x \neq y$  s.t.  $h(x) = h(y)$
- Applications
  - Digital signatures, password verification, key generation ...
  - Present in almost all security systems

# General design approach

- Iterative structure

- Input message is divided into *fixed-length* blocks
- Each block is processed using a *compression function*  $F$

- Design of the compression function

- Block-cipher based
- Customized design “from scratch”
  - the MDx family

# The MDx family of hash functions

- Design philosophy

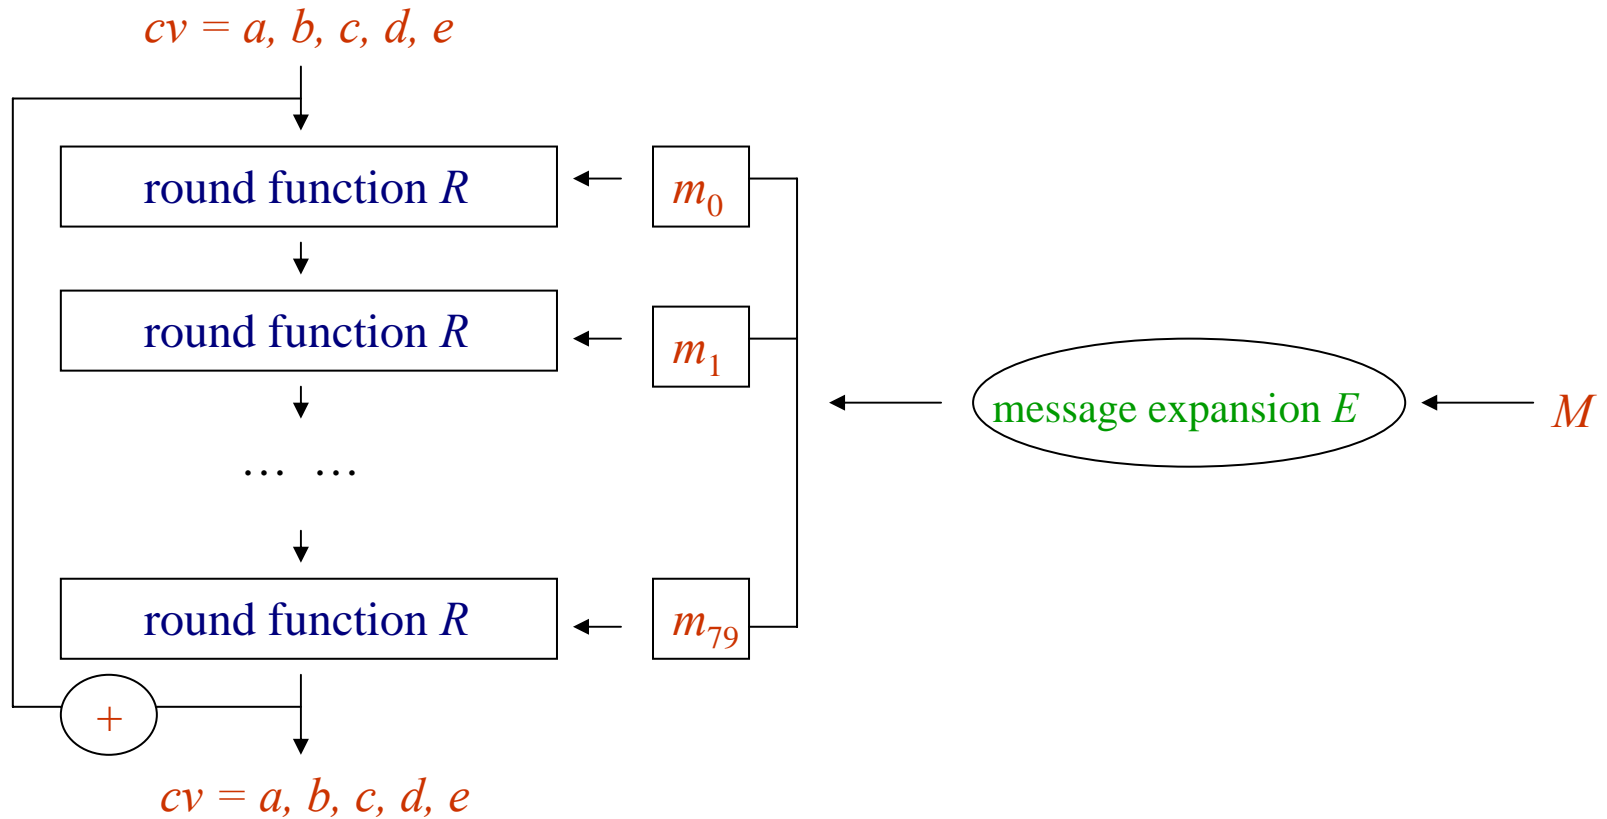

- Using simple operations available on modern computers
  - Easy implementation, good performance

- Most popular ones

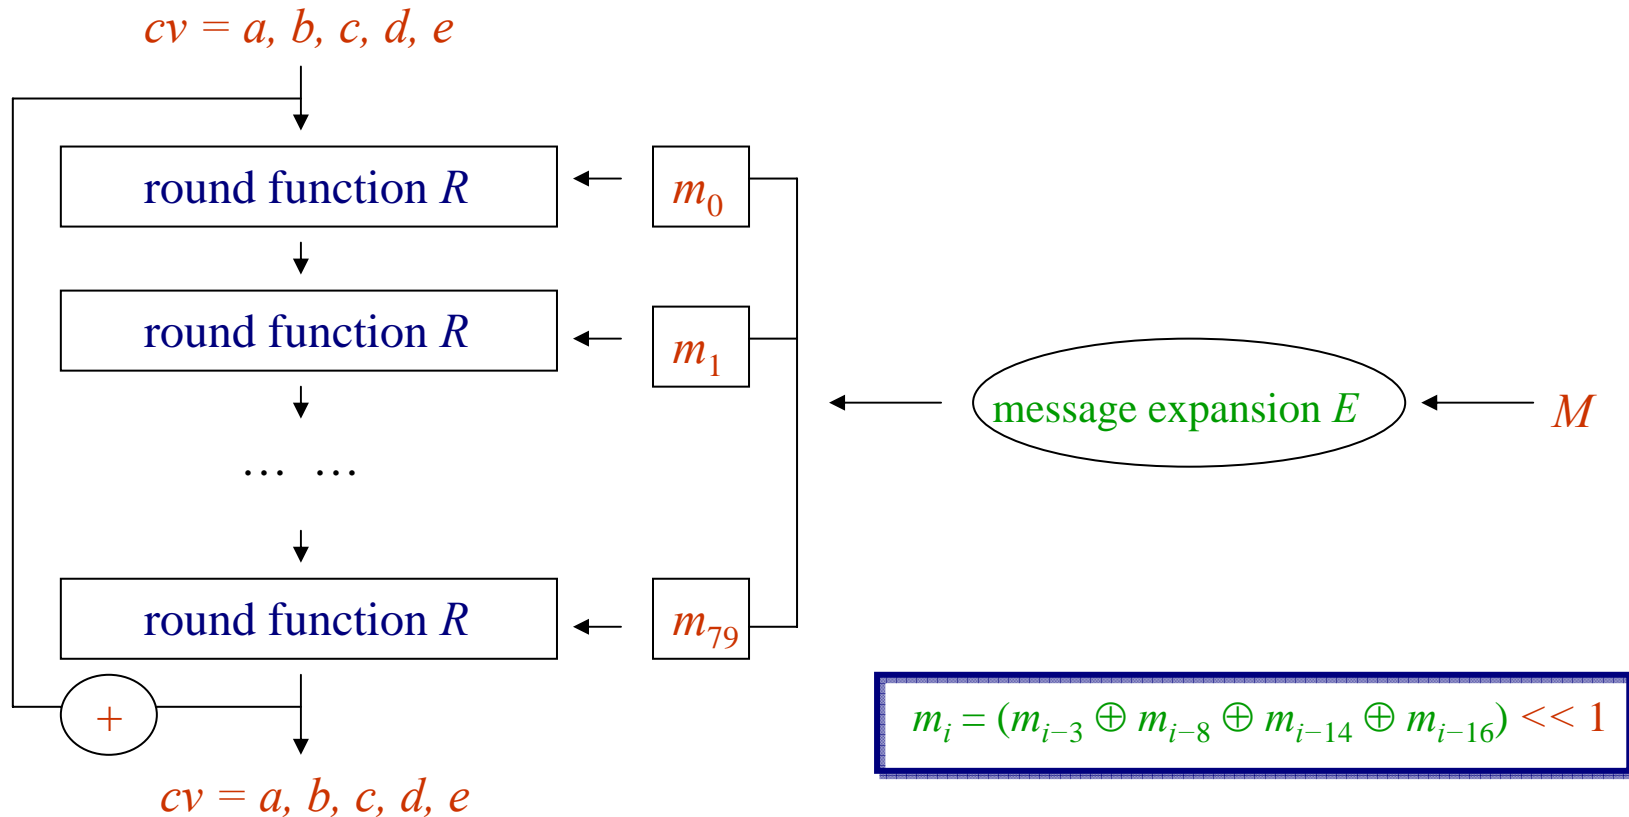

- MD4 (1990)
- MD5 (1991)
  
- SHA-0 (1993)
- SHA-1 (1995)
- SHA-2 (2001)
  - SHA-224, 256, 384, 512

# Compression function of SHA-0 & SHA-1

# Compression function of SHA-0 & SHA-1

$$m_i = (m_{i-3} \oplus m_{i-8} \oplus m_{i-14} \oplus m_{i-16}) \lll 1$$

SHA-0 doesn't have  $\lll 1$

R:

$$a = (a \lll 5) + f(b, c, d) + e + m_i + k_i$$

$$a \rightarrow b \rightarrow (\lll 30) \rightarrow c \rightarrow d \rightarrow e$$

# Security strengths

- Expected security level
  - Depends on hash output length  $n$
  - One-way:  $2^n$
  - Collision resistant:  $2^{n/2}$
- Security of MDx against collision search attacks

| Hash function | Expected strength | Best known collision attack |
|---------------|-------------------|-----------------------------|
| MD4           | $2^{64}$          | $\sim 3$                    |
| MD5           | $2^{64}$          | $\sim 2^{30+}$              |
| SHA-0         | $2^{80}$          | $2^{39}$                    |
| SHA-1         | $2^{80}$          | $2^{69}$                    |
| SHA-256       | $2^{128}$         | ?                           |

Our new results

# Previous work on SHA-0 & SHA-1

- Chabaud and Joux (Crypto'98)
  - Collision attack on SHA-0, with complexity  $2^{61}$
  - Introduced two useful tools: **local collision** and **disturbance vector**
- Wang (Manuscripts, 97 – 98)
  - Independent analysis on SHA-0
  - **Message modification techniques** and **algebraic analysis**
- Biham and Chen (Crypto'04)
  - Near collision attack on SHA-0, with complexity  $2^{40}$
  - **Neutral bit techniques**
- Biham, Chen, Joux etc. (Crypto'04 Rump, Eurocrypt'05)
  - First real collision of SHA-0 found, with complexity  $2^{51}$
  - Collision attack on SHA-1 reduced to 50+ rounds
  - **Multi-block techniques**
- Rijmen and Oswald (RSA-CT'05)
  - Collision attack on SHA-1 reduced to 53 rounds
  - Analysis using insight from **coding theory**

# Overview of a collision attack: differential style attacks

- Differential attacks were first introduced to analyze block ciphers
- Basic ideas applicable to hash functions
  - difference:  $\Delta x = x \oplus x'$
  - Express a collision of  $F$ 

$$\Delta cv = 0, \Delta M \neq 0 \rightarrow \Delta cv = 0$$
  - Differential path
    - Intermediate differences
    - Holds with some prob  $p$
    - Complexity is about  $1/p$

# Chabaud and Joux's Attack on SHA-0

- Basic idea

- Find *local collision* — a collision spanning a few steps
  - By analyzing round function
- Stack local collisions together to form a global collision
  - By analyzing message expansion

# Local collision of SHA-0

Local collision: a 6-round diff path with  $\Delta cv = 0$  before and after.

| round | $\Delta m_{i-1}$ | $\Delta a_i$ | $\Delta b_i$ | $\Delta c_i$ | $\Delta d_i$ | $\Delta e_i$ |
|-------|------------------|--------------|--------------|--------------|--------------|--------------|
| $i-1$ |                  | 0            | 0            | 0            | 0            | 0            |
| $i$   | *                | *            |              |              |              |              |
| $i+1$ | *                |              | *            |              |              |              |
| $i+2$ | *                |              |              | *            |              |              |
| $i+3$ | *                |              |              |              | *            |              |
| $i+4$ | *                |              |              |              |              | *            |
| $i+5$ | *                | 0            | 0            | 0            | 0            | 0            |

Local collision can start at **any** round. *Probability* is about  $2^{-2} - 2^{-5}$ .

# Disturbance vector (DV) for SHA-0

|       | $\Delta a$ | $\Delta b$ | $\Delta c$ | $\Delta d$ | $\Delta e$ | $x_i$ |
|-------|------------|------------|------------|------------|------------|-------|
| Round | 0          | 0          | 0          | 0          | 0          |       |
| 1     | *          |            |            |            |            |       |
| 2     |            | *          |            |            |            |       |
| ...   | *          |            | *          |            |            |       |
|       |            | *          |            | *          | *          |       |
|       |            |            | *          | *          | *          |       |
|       | ...        | ...        |            |            |            |       |
|       | *          |            | *          | *          | *          |       |
| ...   |            | *          |            | *          | *          |       |
|       |            |            | *          | *          | *          |       |
| 80    | 0          | 0          | 0          | 0          | 0          |       |

- Stack local collisions
  - Need to specify starting points of local collisions

# Disturbance vector (DV) for SHA-0

| Round | $\Delta a$ | $\Delta b$ | $\Delta c$ | $\Delta d$ | $\Delta e$ | $x_i$ |
|-------|------------|------------|------------|------------|------------|-------|
|       | 0          | 0          | 0          | 0          | 0          |       |
| 1     | *          |            |            |            |            | 1     |
| 2     |            | *          |            |            |            | 0     |

| ...   | *          |            |            | *          |            | ...   |
| ...   |            | *          |            |            | *          | 1     |
| ...   |            |            | *          |            |            | ...   |
| ...   | *          |            |            | *          |            | 1     |
| ...   |            | *          |            |            | *          | 0     |
| ...   |            |            | *          |            |            | ...   |
| 80    | 0          | 0          | 0          | 0          | 0          |       |

- DV:  $x_0, x_1, x_2, \dots, x_{79}$ 
  - $x_i = 1$  iff a local collision starts in round  $i$
- DV satisfies message expansion
  - Possible choices:  $2^{16}$
- Three conditions on DV
  - Ensure that local collisions can be put together properly
  - Only 3 vectors left
- What is a good DV?
  - low Hamming weight
  - Higher prob for the path

# Improved collision search attack on SHA-0 — brief description

## 1. Construct differential path

- Select a good DV
  - Search in **less constraint** vector space (**fewer** conditions)
  - HW of the DV is **lower** than those in existing attacks
- Fine tune the differential path

## 2. Boost success probability of the attack

- Apply message modification techniques from the attack on MD5

## ■ Complexity of the attack: $2^{39}$

- Real collisions can be found quickly

# Finding Collisions in the Full SHA-1

CRYPTO 2005  
August 15, 2005

Xiaoyun Wang  
Yiqun Lisa Yin  
Hongbo Yu

# Collision search attack on SHA-1

## 1. Construct differential path

- Leverage on techniques from the attack on SHA-0
  - Local collisions and **generalized** disturbance vectors
- **Search** for low Hamming weight vectors
  - Exploit weakness in SHA-1 message expansion
- **Fine tune** the differential path
  - Exploit weakness in round function

## 2. Boost success probability of the attack

- Apply techniques from the attack on MD5
  - **Derive conditions** associated with the differential path
  - **Modify messages** so that many of the conditions hold with *probability one*
  - **Construct two-block collision** using near collision

# Disturbance vector (DV) for SHA-1

|       | $\Delta a$ | $\Delta b$ | $\Delta c$ | $\Delta d$ | $\Delta e$ | $x_i$      |
|-------|------------|------------|------------|------------|------------|------------|
| Round | 0          | 0          | 0          | 0          | 0          |            |
| 1     | *          |            |            |            |            | 1000...110 |
| 2     |            | *          |            |            |            | 0000...000 |
| ...   | *          |            |            |            |            | ...        |
|       |            | *          |            |            |            | ...        |
|       |            |            | *          |            |            | ...        |
|       | ...        | ...        |            | *          |            | ...        |
|       | *          |            |            |            |            | 0110...111 |
| ...   |            | *          |            |            |            | ...        |
|       |            |            | *          |            |            | ...        |
|       |            |            |            | *          |            | ...        |
| 80    | 0          | 0          | 0          | 0          | 0          | ...        |

- Change from SHA-0
  - Each  $x_i$  is now 32 bits
    - Due to  $\ll 1$  in message expansion
  - Search space:  $2^{16 \times 32}$

# Search for good DVs for SHA-1

- What are the difficulties?
  - Search space is huge:  $2^{512}$
  - Hamming weight of DV grows much faster than SHA-0
    - 50+ round seems to be the limit for breaking the  $2^{80}$  barrier
- Main ideas
  - Use heuristic to narrow the search
    - Assume special forms for DV
  - Take advantage of asymmetry in message expansion
  - Remove *all* three conditions on DV
- Matching lower bound
  - $HW \geq 25$  (Jutla, Patthak, last week)

# Construct a valid differential path

- What are the difficulties?
  - Local collisions can no longer be stacked together
    - Since all conditions on DV are removed
- How to solve the problem?
  - Derive an **impossible** path using DV and local collisions
  - Identify **un-wanted** bit differences
  - **Cancel** these differences in two ways
    - Carry expansion to **introduce** a new difference
    - Boolean function to **absorb** a difference

# Derive conditions for differential path

- Conditions on chaining variables
  - Control carry expansion
    - E.g., setting  $a_{i,5} = 1, a_{i,6} = 0$  expands  $\Delta a_{i-1} = 2^5$  to  $\Delta a_i = -2^5 + 2^6$
  - Control output difference of  $f = (b \wedge c) \vee (\neg b \wedge d)$ 
    - E.g., setting  $c = d$  ensures  $[\Delta b = 1 \rightarrow \Delta f = 0]$
- Conditions on message words
  - Set relations among message bits
    - Eliminate carry effect in local collision to increase success prob.
- **Note:** Carry can be good or bad
  - Setting the right conditions can help both ways

# Message modification

- Conditions on  $a_i$  are of a general form
  - $a_{i,j} = 0, 1$
- Basic idea
  - Round function:  $a_i = T + m_{i-1}$
  - Set  $a_{i,j} = \text{the bit}$ , and compute  $m_{i-1} = a_i - T$
  - So the condition holds with  $p=1$
  - Works when  $m_i$ 's are independent
- More complex methods: Multi-message modification
  - Use of local collisions

# Breaking the $2^{80}$ barrier

- One-block collision
  - 75-round SHA-1: complexity is less than  $2^{80}$ 
    - Already show that “security margin” is not enough
- Near collision
  - 80-round SHA-1: complexity is about  $2^{68}$
- Two-block collision
  - Use two near collisions
  - Set output differences so that they offset with *probability one*
    - No increase in search complexity
  - Attack complexity is  $2^{69}$

# Summary — cryptanalyst's viewpoint

- **Message modification** techniques
  - Very effective for boosting success probability
  - Idea applies to any key-less hash function
- Extensive use of local collisions
  - Basic building block for a differential path
  - Also useful in **multi-message modification**
    - Like a local disturbance without affect global computation
- Manipulation of differential path
  - “Front-loading” path tailored to **message modification**
  - Turn an impossible path into a possible one
- All techniques leverages on each other

# Summary — designer's viewpoint

- The MDx family all follows similar design approaches
  - The M-D iterative structure
    - Some weaknesses found (Joux; Kelsey, Schneier)
  - Message expansion
    - Not enough avalanche effect, even for SHA-1
  - Round function
    - Non-linear components can actually facilitate attack
- What about the SHA-2 family?
  - Local collision existing with smaller prob. (Hawks, Paddon, Rose)
  - Message expansion is much more complicated
  - More analysis is still needed

Thank you very much!
