

Introduction to Learning

Lecture 2

David Sontag
New York University

Slides adapted from Luke Zettlemoyer, Vibhav Gogate,
Pedro Domingos, and Carlos Guestrin

Hypo. Space: Degree-N Polynomials

We measure error using a *loss function* $L(y, \hat{y})$

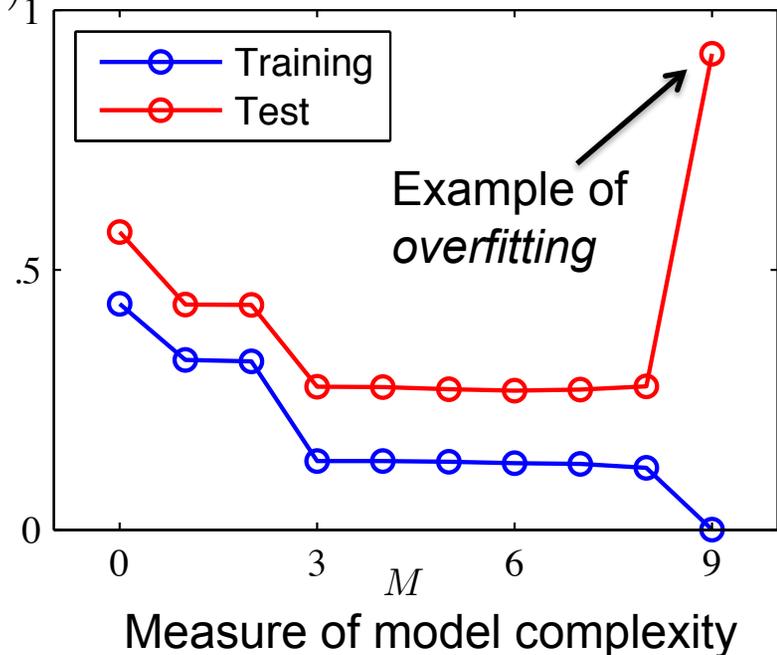

For regression, a common choice is squared loss:

$$L(y_i, f(x_i)) = (y_i - f(x_i))^2 \quad \text{Squared error}$$

The *empirical loss* of the function f applied to the training data is then:

$$\frac{1}{N} \sum_{i=1}^N L(y_i, f(x_i)) = \frac{1}{N} \sum_{i=1}^N (y_i - f(x_i))^2$$

Learning curve

Occam's Razor Principle

- William of **Occam**: Monk living in the 14th century
- Principle of parsimony:

“One should not increase, beyond what is necessary, the number of entities required to explain anything”

- When **many** solutions are available for a given problem, we should select the **simplest** one
- But what do we mean by **simple**?
- We will use **prior knowledge** of the problem to solve to define what is a simple solution

Example of a prior: smoothness

[Samy Bengio]

Key Issues in Machine Learning

- How do we choose a hypothesis space?
 - Often we use **prior knowledge** to guide this choice
- How can we gauge the accuracy of a hypothesis on unseen data?
 - **Occam's razor**: use the *simplest* hypothesis consistent with data! This will help us avoid overfitting.
 - **Learning theory** will help us quantify our ability to **generalize** as a function of the amount of training data and the hypothesis space
- How do we find the best hypothesis?
 - This is an **algorithmic** question, the main topic of computer science
- How to model applications as machine learning problems?
(engineering challenge)

Binary classification

- **Input:** email
- **Output:** spam/ham
- **Setup:**
 - Get a large collection of example emails, each labeled “spam” or “ham”
 - Note: someone has to hand label all this data!
 - Want to learn to predict labels of new, future emails
- **Features:** The attributes used to make the ham / spam decision
 - Words: FREE!
 - Text Patterns: \$dd, CAPS
 - Non-text: SenderInContacts
 - ...

Dear Sir.

First, I must solicit your confidence in this transaction, this is by virtue of its nature as being utterly confidential and top secret. ...

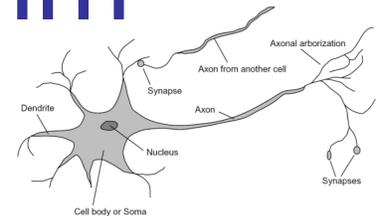

TO BE REMOVED FROM FUTURE MAILINGS, SIMPLY REPLY TO THIS MESSAGE AND PUT "REMOVE" IN THE SUBJECT.

99 MILLION EMAIL ADDRESSES
FOR ONLY \$99

Ok, I know this is blatantly OT but I'm beginning to go insane. Had an old Dell Dimension XPS sitting in the corner and decided to put it to use, I know it was working pre being stuck in the corner, but when I plugged it in, hit the power nothing happened.

The perceptron algorithm

- 1957: Perceptron algorithm invented by Rosenblatt

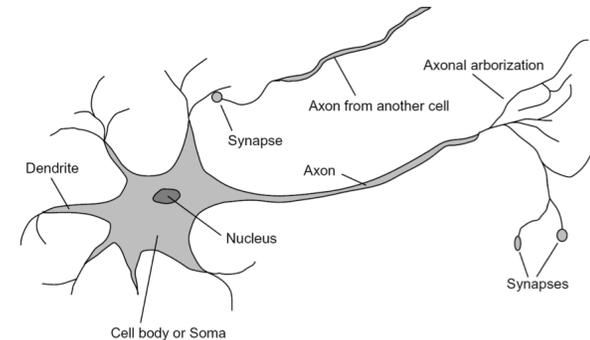

Wikipedia: “A handsome bachelor, he drove a classic MGA sports... for several years taught an interdisciplinary undergraduate honors course entitled "Theory of Brain Mechanisms" that drew students equally from Cornell's Engineering and Liberal Arts colleges...this course was a melange of ideas .. experimental brain surgery on epileptic patients while conscious, experiments on .. the visual cortex of cats, ... analog and digital electronic circuits that modeled various details of neuronal behavior (i.e. the perceptron itself, as a machine).”

- Built on work of Hebb (1949); also developed by Widrow-Hoff (1960)
- 1960: Perceptron Mark 1 Computer – hardware implementation
- 1969: Minsky & Papert book shows perceptrons limited to *linearly separable* data, and Rosenblatt dies in boating accident
- 1970's: Learning methods for two-layer neural networks

[William Cohen]

Linear Classifiers

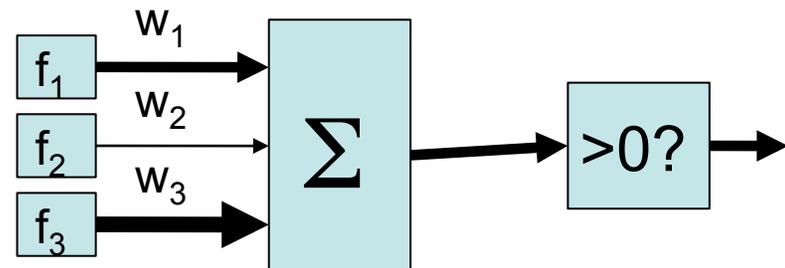

- Inputs are **feature values**
- Each feature has a **weight**
- Sum is the **activation**

Important note: changing notation!

$$\text{activation}_w(x) = \sum_i w_i \cdot f_i(x) = w \cdot f(x)$$

- If the activation is:
 - Positive, output *class 1*
 - Negative, output *class 2*

Example: Spam

- Imagine 3 features (spam is “positive” class):
 - free (number of occurrences of “free”)
 - money (occurrences of “money”)
 - BIAS (intercept, always has value 1)

$$w \cdot f(x)$$

$$\sum_i w_i \cdot f_i(x)$$

x	$f(x)$	w	
“free money”	BIAS : 1 free : 1 money : 1 ...	BIAS : -3 free : 4 money : 2 ...	$(1)(-3) +$ $(1)(4) +$ $(1)(2) +$... = 3

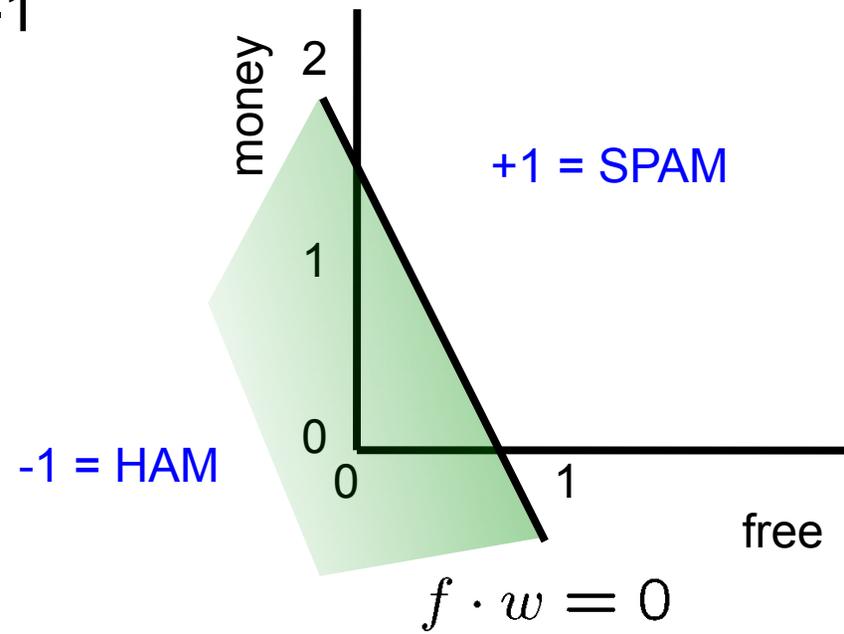

$w \cdot f(x) > 0 \rightarrow$ SPAM!!!

Binary Decision Rule

- In the space of feature vectors
 - Examples are points
 - Any weight vector is a hyperplane
 - One side corresponds to $Y=+1$
 - Other corresponds to $Y=-1$

w

BIAS	:	-3
free	:	4
money	:	2
...	:	

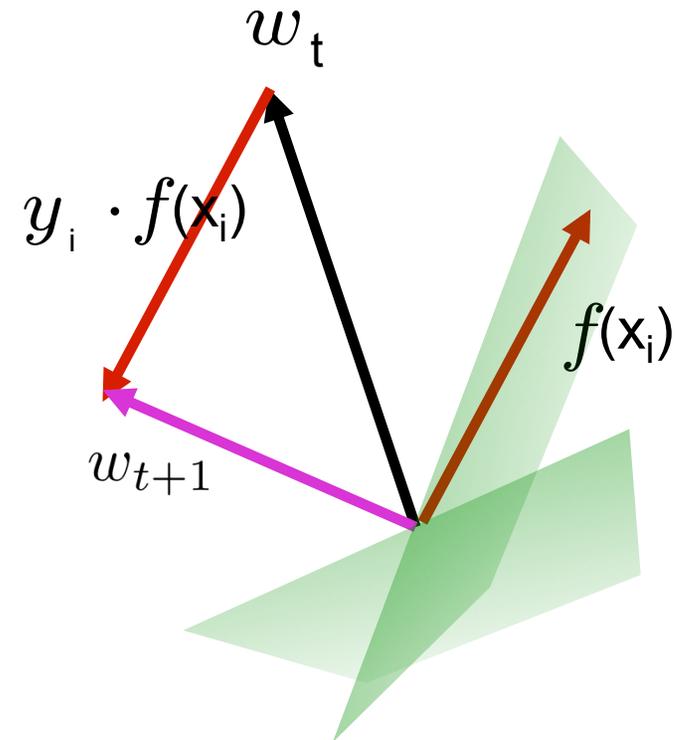

The perceptron algorithm

- Start with weight vector = $\vec{0}$
- For each training instance (x_i, y_i) :
 - Classify with current weights

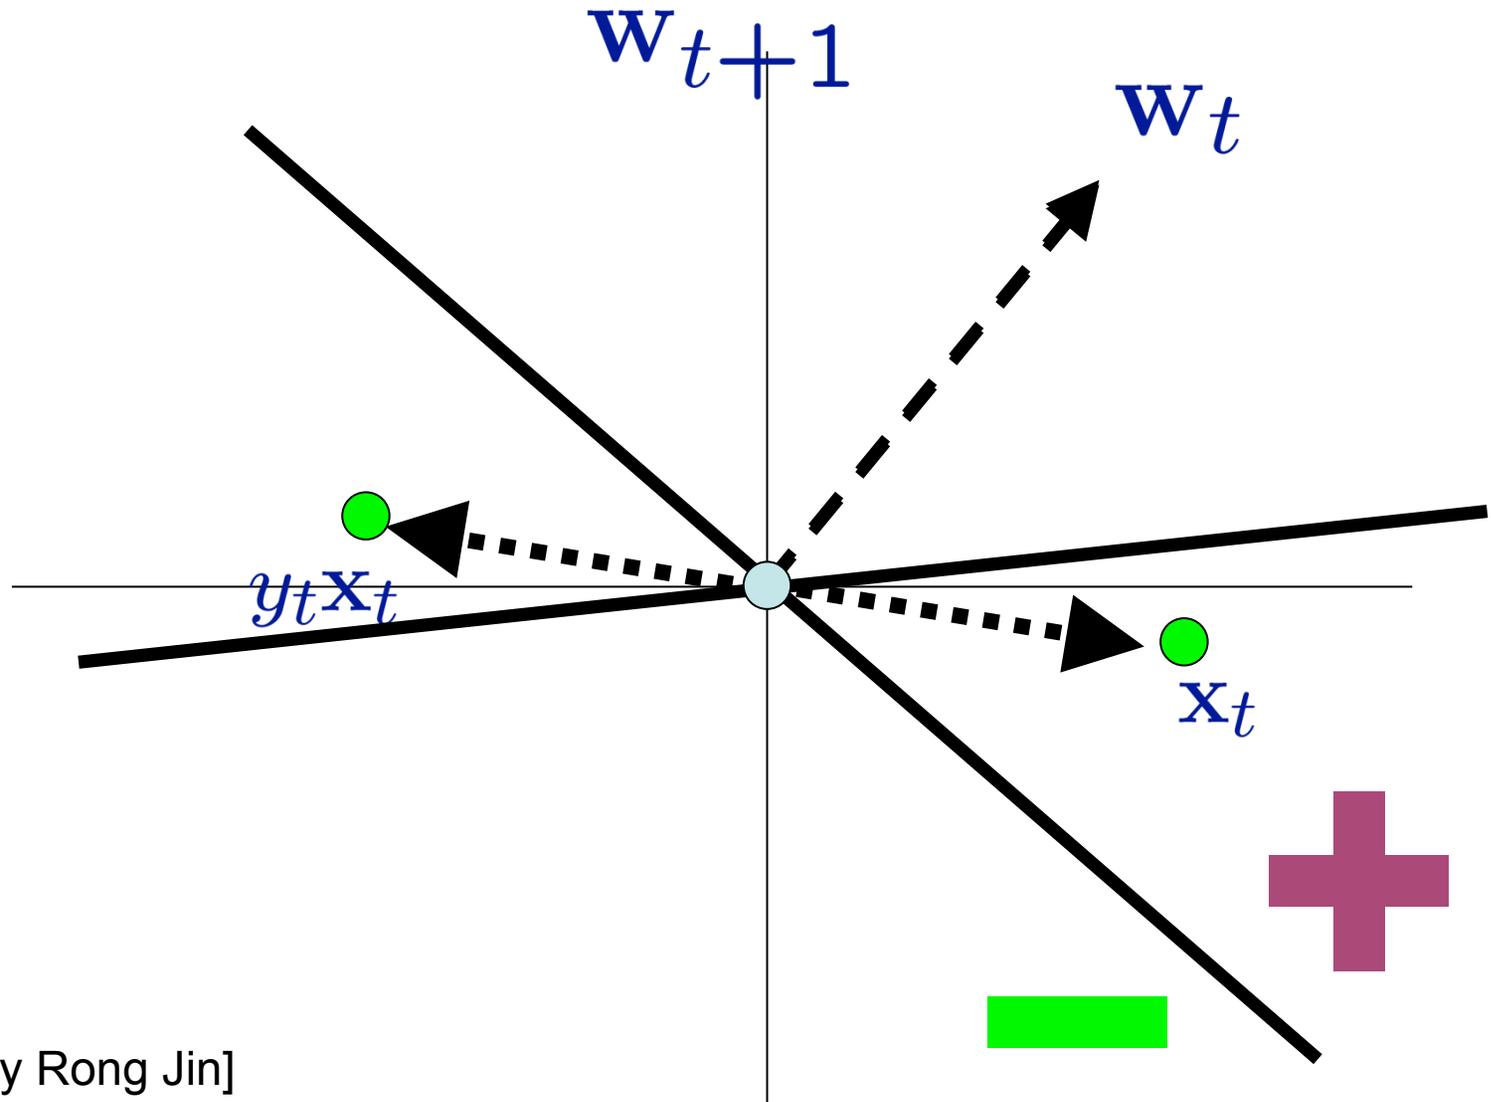

$$y = \begin{cases} +1 & \text{if } w \cdot f(x_i) \geq 0 \\ -1 & \text{if } w \cdot f(x_i) < 0 \end{cases}$$

- If correct (i.e., $y=y_i$), no change!
- If wrong: update

$$w = w + y_i f(x_i)$$

Geometrical Interpretation

[Slide by Rong Jin]

What questions should we ask about a learning algorithm?

- What is the perceptron algorithm's running time?
- If a weight vector with small training error exists, will perceptron find it?
- How well does the resulting classifier generalize to unseen data?

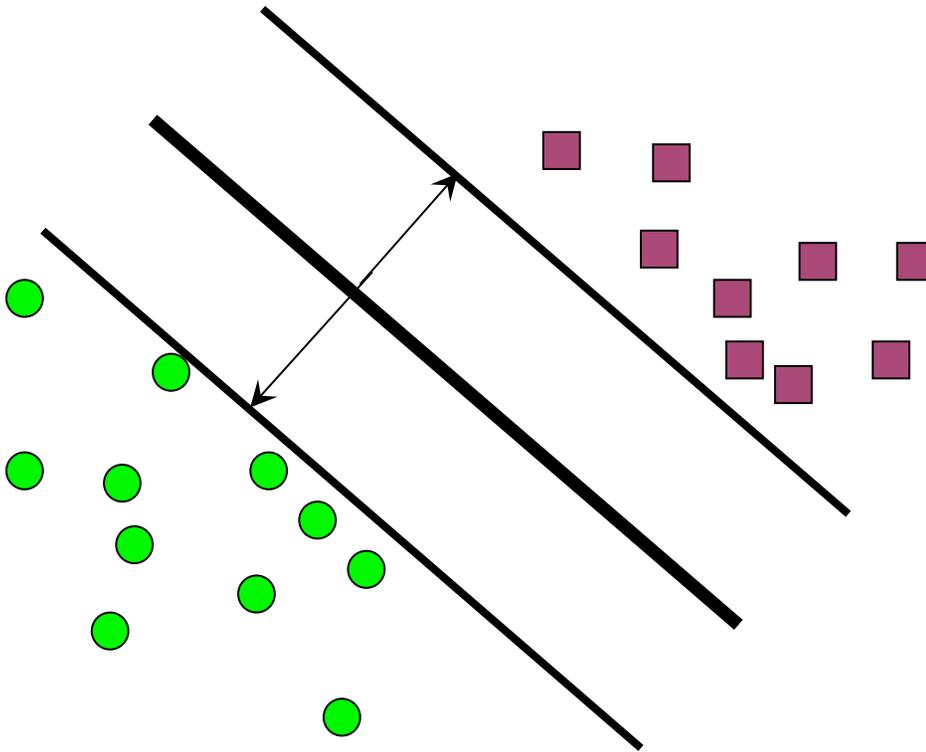

Linearly Separable

$\exists w$ such that $\forall t$

$$y_t(w \cdot x_t) \geq \gamma > 0$$

Called the *functional margin*
with respect to the training set

Equivalently, for $y_t = +1$,

$$w \cdot x_t \geq \gamma$$

and for $y_t = -1$,

$$w \cdot x_t \leq -\gamma$$

Mistake Bound for Perceptron

- Assume the data set D is linearly separable with *geometric* margin γ , i.e.,

$$\exists w^* \text{ s.t. } \|w^*\|_2 = 1 \text{ and } \forall t, y_t(w \cdot x_t) \geq \gamma$$

- **Assume** $\|x_t\|_2 \leq R, \forall t$
- **Theorem**: The maximum number of mistakes made by the perceptron algorithm is bounded by R^2 / γ^2

Proof by induction

Assume we make a mistake for (\mathbf{x}_t, y_t)

$$\|\mathbf{w}_{t+1}\|_2^2 = \|\mathbf{w}_t + y_t \mathbf{x}_t\|_2^2 \leq \|\mathbf{w}_t\|_2^2 + R^2$$

$$\mathbf{w}_{t+1}^\top \mathbf{w}^* = \mathbf{w}_t^\top \mathbf{w}^* + y_t \mathbf{x}_t^\top \mathbf{w}^* \geq \mathbf{w}_t^\top \mathbf{w}^* + \gamma$$

$$\|\mathbf{w}_t\|_2^2 \leq M_t \cdot R^2$$

$$\mathbf{w}_t^\top \mathbf{w}^* \geq M_t \cdot \gamma$$

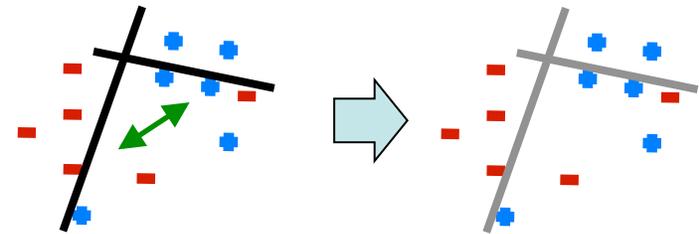

$$M_t \leq \frac{R^2}{\gamma^2}$$

(full proof given on board)

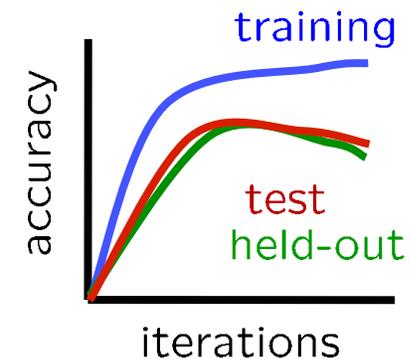

[Slide by Rong Jin]

Problems with the perceptron algorithm

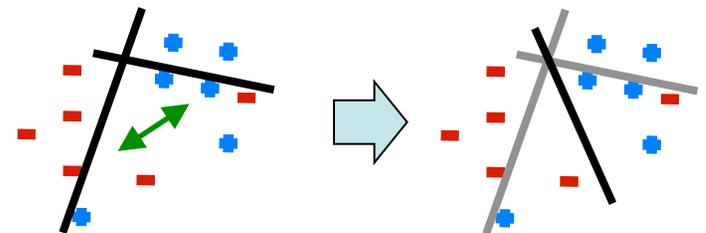

- If the data isn't linearly separable, no guarantees of convergence or training accuracy

- Even if the training data is linearly separable, perceptron can overfit

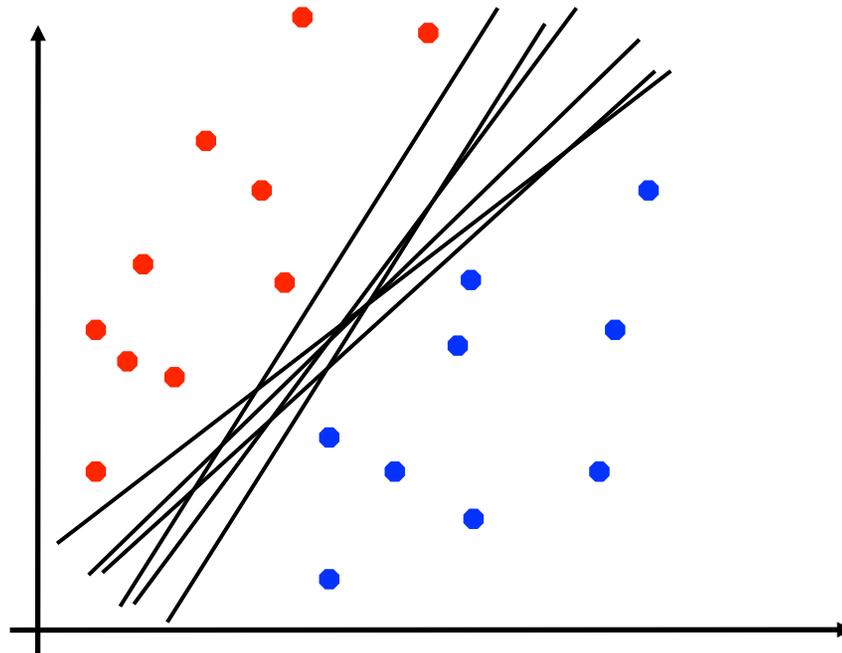

- **Averaged** perceptron is an algorithmic modification that helps with both issues
 - Averages the weight vectors across all iterations

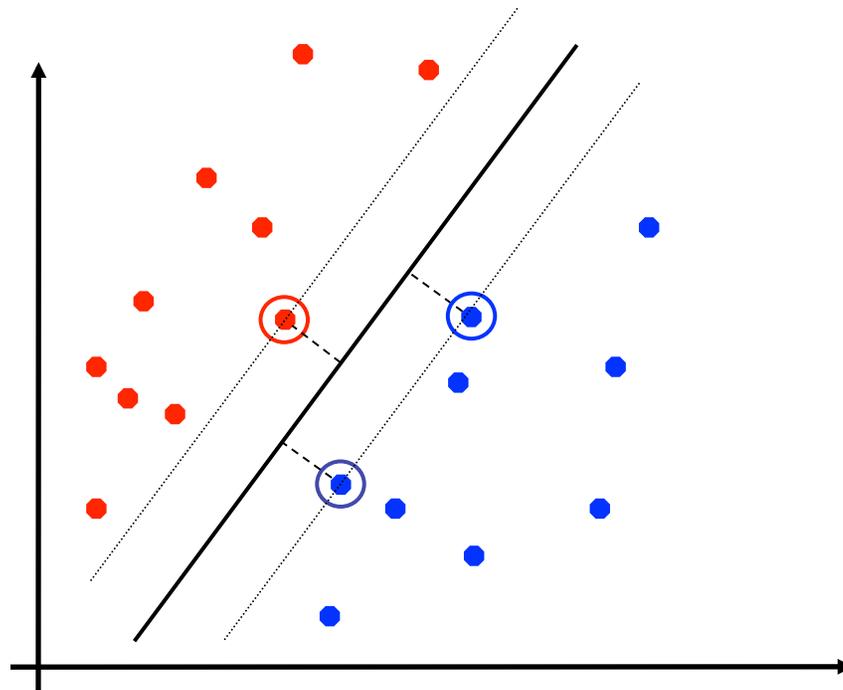

Linear Separators

- Which of these linear separators is optimal?

Next week: Support Vector Machines

- SVMs (Vapnik, 1990's) choose the linear separator with the **largest margin**

- Good according to intuition, theory, practice

ML Methodology

- **Data:** labeled instances, e.g. emails marked spam/ham
 - Training set
 - Held out set (sometimes call Validation set)
 - Test set

Randomly allocate to these three, e.g. 60/20/20

- **Features:** attribute-value pairs which characterize each x
- **Experimentation cycle**
 - Select a hypothesis f
(Tune hyperparameters on held-out or *validation* set)
 - Compute accuracy of test set
 - Very important: never “peek” at the test set!
- **Evaluation**
 - Accuracy: fraction of instances predicted correctly
