GOO Reference Manual v43

Jonathan Bachrach MIT AI Lab

September 5, 2002

1 Introduction

 \mathcal{GOO} is a dynamic type-based object-oriented language. It is designed to be simple, productive, powerful, extensible, dynamic, efficient and real-time. It heavily leverages features from many earlier languages. In particular, it attempts to be a simpler, more dynamic, lisp-syntaxed Dylan [4] and an object-oriented Scheme [3]. \mathcal{GOO} 's main goal is to offer the best of both scripting and delivery languages while at the same time incorporating an extreme back-to-basics philosophy. \mathcal{GOO} is freely available from www.googoogaga.org under GPL. This manual is preliminary and relies on an understanding of Scheme and Dylan.

1.1 Notation

Throughout this document \mathcal{GOO} objects are described with definitions of the following form:

Name	Signature	\mathcal{N}
Documentatio	n	

where the rightmost kind field has a one letter code as follows:

N	Notation	\mathcal{N}
L	Lexical	\mathcal{N}
S	Syntax	\mathcal{N}
G	Generic	\mathcal{N}
М	Method	\mathcal{N}
F	Function	\mathcal{N}
С	Class	\mathcal{N}
Р	Property	\mathcal{N}
I	Instance	\mathcal{N}
K	Command	\mathcal{N}

1.2 Lexical Structure

The lexical structure is mostly the same as Scheme [3] with the notable exceptions being that identifiers can start with numeric digits if they are clearly distinguishable from floating point numbers and no syntax is provided for specifying improper lists. Furthermore, vertical bars are tokenized immediately and separately and have special meaning within lists, providing syntactic sugar for typed variables.

The following is a very brief and incomplete description of how characters are tokenized into s-expressions, where s-expressions are either tokens or lists of s-expressions:

<i>i</i>	Line comment	\mathcal{N}
#/ /#	Nested comment	\mathcal{N}

. + - [0-9]+	Number	\mathcal{N}
#e #i #b #o #d #x	Special number	\mathcal{N}
#t #f	Logical	\mathcal{N}
#\name	Character	\mathcal{N}
[a-zA-Z0-9]+	Identifier	\mathcal{N}
()	List	\mathcal{N}
#()	Tuple	\mathcal{N}
#[]	Vector	\mathcal{N}
" "	String	\mathcal{N}
\ <i>c</i>	Special character's within strings	\mathcal{N}
x t	Typed variable within list $\equiv (x t)$.	\mathcal{N}
#	Escaped vertical bar.	\mathcal{N}
{ }	Lightweight function syntax.	\mathcal{N}
'[' ']'	Collection indexing and slicing.	\mathcal{N}

1.3 Meta Syntax

 \mathcal{GOO} 's syntax is described almost entirely as \mathcal{GOO} patterns. \mathcal{GOO} patterns in turn are defined with a quasiquote metasyntax. Pattern variables are prefixed with a "," or ",e" to indicate the matching of one or many elements respectively. The default is for a pattern variable to match one or many s-expressions. Alternatively, a pattern variable's shape may be defined with another pattern. The ,name shape is builtin and matches only identifiers. The '['...']' metasyntax is used to indicate optional patterns, '...' is used to indicate zero or more of the preceding pattern element, and ## is used to denote infix string concatenation. Finally, in this manual, uppercase indicates a special form or macro.

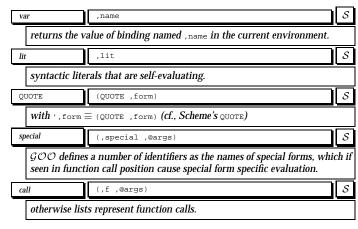

1.4 Conventions

ual: Type variable \mathcal{N} ' < ' . . . ' > ' \mathcal{N} /*/ ... /* Global variable \mathcal{N} ...'?' Predicate Destructive function \mathcal{N} ...'!' ...'-setter' Setter

The following naming conventions are used throughout this man-

2 Expressions

Once tokenized, \mathcal{GOO} evaluates s-expressions in the usual lisp manner:

3 Namespaces and Bindings

 \mathcal{GOO} is a lexically scoped language. Bindings contain values and are looked up by name. Lexical bindings are visible from only particular textual ranges in a program. Lexical bindings shadow visible bindings of the same name.

At the topmost level, \mathcal{GOO} provides simple modules that map from names to bindings. Each file introduces a new module with the same name as the file. Nested modules are supported by way of slashes in module names. Modules can import bindings exported by other modules, but currently there is no way to selectively exclude or rename imported bindings. Furthermore, no cycles can occur in the module use heterarchy.

DV	(DV ,var ,form)
defines a glo (cf. Scheme?	bal variable named (var-name ,var) with an initial value ,form s DEFINE).
DEF	(DEF ,var ,val) ${\cal S}$
locally bind context of th	s ,var to ,val and evaluates remainder of current body in the nat binding.
	(DEF (TUP ,var) ,val)
	ding can also be specified using TUP on the lhs of a DEF binding. (DEF (TUP x y) (TUP 1 2))
LET	(LET ((,var ,val)) ,@body)
\equiv (seq (def	7 ,var ,val) ,@body)
where	
,var	\equiv ,name (,name ,type) \mathcal{L}
with ,name	,type \equiv (,name ,type) within lists.
with , name	<pre> ,type ≡ (,name ,type) within lists. (SET ,name ,form)</pre>
SET	
SET	(SET ,name ,form)
SET sets , name b	(SET ,name ,form)
SET sets , name b	(SET ,name ,form) S inding to value of evaluating ,form (cf. Scheme's SET!) (SET (,name ,@args) ,form) S
SET SET (, name b) (, name #4 USE loads the mo	(SET ,name ,form) S inding to value of evaluating ,form (cf. Scheme's SET!) (SET (,name ,@args) ,form) S # -setter ,form ,@args)
SET SET (, name b) (, name #4 USE loads the mo	(SET , name , form) S inding to value of evaluating , form (cf. Scheme's SET:) (SET (, name ,@args) , form) S # -setter , form ,@args) (USE , name) S odule , name (if it hasn't been loaded already) and aliases all the
SET Sets , name by E (, name ## USE loads the mo exported bin EXPORT	(SET , name , form) S inding to value of evaluating , form (cf. Scheme's SET!) (SET (, name ,@args) , form) S # -setter , form ,@args) S (USE , name) S odule , name (if it hasn't been loaded already) and aliases all the drings into the current namespace.

same as USE plus reexports all imported bindings.

4 Program Control

 ${\cal GOO}$ provides a variety of program control constructs including function calls, conditional execution, and nonlocal control flow.

SEQ	(SEQ ,@forms)	
evaluates for Scheme's BEG	The sequentially and returns values of evaluating last form T_{N}	n (e
Scheme 3 BEG	(SEQ)	I ,
naturna falca		-
returns false		_
IF	(IF ,test ,then [,else])

Dylan's SELECT and Sche ach key is evaluated, thus symbols must be quoted. The de CASE form is ==. (OPF ,place ,expr) - ,place) (SET ,place ,expr)), where ,place is evalue or example, (OPF x (+ - 1)) = (SET x (+ x 1)). (SWAPF ,x ,y) r tmp ,x) (SET ,x ,y) (SET ,y tmp)), where ,x and ,y ly once. (ROTF ,x ,y ,@places) (XOTF ,x ,y ,@places) ,x ,y ,@places) (TUP ,y ,@places ,x)) where ,x, ,y, we evaluated only once and (SET (TUP) val) stand imment. (,f ,@args) and then ,@args in left to right order and then calls ,f wit guments.</pre>	/hi fau fau an an b t

evaluates (SEQ , @body) with an exit function of a single parameter, x, bound to ,name that if called, will cause ESC to return the value of x (cf. Dylan's BLOCK/RETURN). It is illegal to call the exit function after the execution of the creating ESC form (i.e., no upward continuations).

FIN	(FIN ,protected ,@cleanups)
W. BL	nsures that (SEQ ,@cleanups) is evaluated whether or not an ESC up- rards exit is taken during the dynamic-extent of ,protected (cf. Dylan's SOCK/CLEANUP form and CL'S UNWIND-PROTECT). The result of a FIN form is ne result of evaluating its protected form.
ASSE	RT (ASSERT ,test ,message ,@args)
Ξ	(UNLESS ,test (ERROR ,message ,@args))

5 Types, Classes and Properties

 \mathcal{GOO} types categorize objects. Types are first class. They are used to annotate bindings. Binding types restrict the type of objects bindable to associated bindings.

 \mathcal{GOO} supports the following types in order of specificity (with the exact ordering defined in Appendix B):

- Singleton types specify a unique instance,
- *Classes* and *properties* specify the structure, inheritance, and initialization of objects. Every object is a direct instance of a particular class,
- Product types specify a cross product of types,
- Subclass types specify a lineage of classes, and
- Union types specify a union of types.

The basic type protocol is:

51		
<type></type>	(<any>)</any>	\mathcal{C}
isa?	(x <any> y <type> => <log>)</log></type></any>	${\mathcal G}$
subtype?	(x <type> y <type> => <log>)</log></type></type>	${\cal G}$
returns tru	e iff x is a subtype of y.	
new	(type <type> prop-inits)</type>	G

creation protocol taking type and creation options where prop-inits contains getter / initial value pairs.

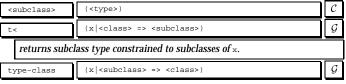

5.1 Singletons

Singleton types match exactly one value using ==. Singletons are the most specific types.

<singleton></singleton>	(<type>)</type>	\mathcal{C}
t=	(x <any> => <singleton>)</singleton></any>	\mathcal{G}
returns singl	eton constrained to x.	
type-object	(x <singleton> => <any>)</any></singleton>	\mathcal{G}
object that singleton type matches.		

5.2 Subclasses

Subclass types match classes and their subclasses. They are quite useful in situations that involve class arguments that need to be further constrained.

object that subclass type matches.

5.3 Unions

Union types represent the disjunction of types. In conjunction with singleton types, they can be used to represent C-style $_{enum}$'s.

<union></union>	(<type>)</type>	\mathcal{C}
t+	(types => <union>)</union>	${\mathcal G}$
returns unio	n type representing disjunction of types.	
union-elts	(x <union> => <seq>)</seq></union>	${\mathcal G}$
types that un	nion type matches.	
types that un	nion type matches. (type <type> => <union>)</union></type>	\mathcal{F}

5.4 Product

Product types represent tuples formed as the cartesian product of types. They are often used to describe multiple value return types.

<product></product>	(<type>)</type>
t*	(types => <product>)</product>
returns produ	ict type specifying the cross product of types.
product-elts	(x <product> => <seq>)</seq></product>
types that pro	oduct type matches.

5.5 Classes

Classes are types that specify an inheritance relationship and can have associated structured data through properties.

<class></class>	(<type>)</type>	\mathcal{C}
class-name	(x <class> => (t? <sym>))</sym></class>	${\mathcal{G}}$
returns class	name or false otherwise.	
class- parents	(x <class> => <seq>)</seq></class>	\mathcal{G}
direct superc	lasses.	
class- ancestors	(x <class> => <seq>)</seq></class>	\mathcal{G}
class precede	nce list including this class. See Appendix A for details.	
class- direct-props	(x <class> => <seq>)</seq></class>	\mathcal{G}
properties de	fined directly on this class.	
class-props	(x <class> => <seq>)</seq></class>	\mathcal{G}
properties de	fined on this class or any superclass.	
class- children	(x <class> => <seq>)</seq></class>	\mathcal{G}
direct subcla	sses.	
DC	(DC ,name (,@parents))	\mathcal{S}
defines a clas	ss named ,name with direct parents ,@parents	
new	(type <class> prop-inits)</class>	\mathcal{M}
	example, (new <point> point-x 1 point-y 2) creates a point-y 2) creates</point>	

5.5.1 Properties

Properties are named data associated with classes. Their values are accessed exclusively through generic functions, called getters and setters. Descriptions of properties are instances of <prop>. Property values can either be specified at creation time with keyword arguments, by calling a property setter, or through a property initialization function called lazily the first time a getter is called if the property is otherwise uninitialized. Property initialization functions are called with a single argument, the object under construction.

<prop></prop>	(<any>)</any>
prop-owner	(x <prop> => <any>)</any></prop>
class on whi	ch property was directly defined.
prop-getter	(x <prop> => <gen>)</gen></prop>
reader access	sor generic.
prop-setter	(x <prop> => <gen>)</gen></prop>
writer access	sor generic.
prop-type	(x <prop> => <type>)</type></prop>
type constra	ining property value.
prop-init	(x <prop> => <fun>)</fun></prop>
lazy initializ	ration function.
find-getter	(c <class> getter <gen> => <met>)</met></gen></class>
finds getter	method defined on given class.
find-setter	(c <class> setter <gen> => <met>)</met></gen></class>
finds setter i	nethod defined on given class.
prop-bound?	(x g <gen> => <log>)</log></gen>
returns true	if property with getter ${}_{\tt G}$ is bound in instance ${}_{\tt X}$.
	(owner getter <gen> setter <gen></gen></gen>
add-prop	type <type> init <fun>)</fun></type>
	s a one parameter function that returns the initial value for the scalled lazily with the new instance as the argument.
DP	(DP ,name (,oname ,owner => ,type) [,@init])
"-setter", t	erty to ,owner with getter named ,name, setter named ,name ## ype ,type, and optionally initial value ,init. The initial value valuated lazily when prop's value is first requested.

6 Functions

All operations in \mathcal{GOO} are functions.

Functions accept zero or more arguments, and return one value. The parameter list of the function describes the number and types of the arguments that the function accepts, and the type of the value it returns.

There are two kinds of functions, methods and generic functions. Both are invoked in the same way. The caller does not need to know whether the function it is calling is a method or a generic function.

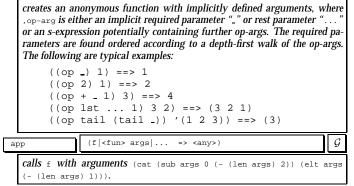

A method is the basic unit of executable code. A method accepts a number of arguments, creates local bindings for them, executes an implicit body in the scope of these bindings, and then returns a value.

A generic function contains a number of methods. When a generic function is called, it compares the arguments it received with the parameter lists of the methods it contains. It selects the most ap-

propriate method and invokes it on the arguments. This technique of method dispatch is the basic mechanism of polymorphism in \mathcal{GOO} .

All GOO functions are objects, instances of <fun>. Generic functions are instances of <gen> and methods are instances of <met>.

<fun> fun-name</fun>	(<any>)</any>	c
fun-name	(x (func -> (+2 (gum>)))	C
not some the s	(x <fun> => (t? <sym>))</sym></fun>	\mathcal{P}
	name of function or false if unavailable.	
fun-names	(x <fun> => <lst>)</lst></fun>	\mathcal{P}
returns the n	names of parameters of x or () if unavailable.	1
fun-specs	(x < fun> => <lst>)</lst>	\mathcal{P}
returns the s	pecializers of x.	
fun-nary?	(x <fun> => <log>)</log></fun>	\mathcal{P}
returns true	iff the function takes optional arguments.	
fun-arity	(x <fun> => <int>)</int></fun>	\mathcal{P}
returns ×'s n	umber of required arguments.	
fun-val	(x <fun> => <type>)</type></fun>	\mathcal{P}
returns the r	eturn type of x.	
FUN	(FUN ,sig ,@body)	S
((fur ((fur ((fur ((fur ((fur	<pre>ctions and their application: n (x) x) 1) ==> 1 n (x <int> => <int>) x) 2) ==> 2 n (x) x) 1 2 3) ==> (1 2 3) n (x y) y) 1 2 3) ==> (2 3) n (x => (tup <int>))) (tup x)) 1) up 1)</int></int></int></pre>

6.1 Generics

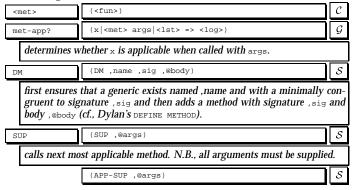

Generic functions provide a form of polymorphism allowing many implementation methods with varying parameter types, called *specializers*. Methods on a given generic function are chosen according to applicability and are then ordered by specificity. A method is applicable if each argument is an instance of each corresponding specializer. A method A is more specific than method B if all of A's specializers are subtypes of B's. During method dispatch three cases can occur:

- if no methods are applicable then a no-applicable-method error is signaled,
- if methods are applicable but are not orderable then an ambiguous-method error is signaled,
- if methods are applicable and are orderable then the most specific method is called and the next methods are established.

<gen></gen>	(<fun>)</fun>			
fun-mets	(x <gen> => <lst>)</lst></gen>			
returns ×'s m	ethods.			
gen-add-met	(x <gen> y <met> => <gen>)</gen></met></gen>			
adds method	y to generic x.			
ord-app-mets	(x <gen> args => (tup ord <lst> amb <lst>))</lst></lst></gen>			
returns both the list of sorted applicable methods and any ambiguous methods when generic $_{\rm x}$ is called with arguments args.				
DG	(DG ,name ,sig)			
defines a bind	ling with name , name bound to a generic with signature , sig.			

6.2 Methods

Methods are \mathcal{GOO} 's code objects. Methods can optionally be added to generics.

applies next most applicable method. N.B., all arguments must be supplied.

6.3 Macros

Macros provide a facility for extending the base syntax of \mathcal{GOO} . The design is based on quasiquote code templates and a simple list pattern matching facility. Macros are currently unhygienic, and users are required to use gensym to avoid name collisions.

QUASIQUOTE	(QUASIQUOTE ,@qq-forms)	\mathcal{S}
	selective evaluation using UNQUOTE and SPLICING-UNQUOTE eme's QUASIQUOTE), abbreviated ".".	(cf.
UNQUOTE	(UNQUOTE ,form)	\mathcal{S}
evaluates , fo	form in the midst of a quasiquote expression, abbreviated ",	".
SPLICING- UNQUOTE	(SPLICING-UNQUOTE ,form)	S
evaluates ,fo abbreviated	form in the midst of a quasiquote expression and splices is ", $@$ ".	t in,
MATCH	(MATCH ,exp (,pat ,val))	\mathcal{S}
much the san	al corresponding to first ,pat matching ,exp. The pattern me as QUASIQUOTE and can contain either UNQUOTE 'd variable come variables. For example, CH '(1 2) ((,a ,b) (lst a b))) \rightarrow (1 2) CH '(1 2) ((,a ,@b) (lst a b))) \rightarrow (1 (2)	es or
DS	(DS ,pattern ,@body)	\mathcal{S}
,®body. The variables dur (DS `(if	acro matching pattern ,pattern and expanding accordin pattern matching occurs as in MIF and makes available pat ring the evaluation of (SEQ ,@body). For example, (unless ,test ,@body) (not ,test) (seq ,@body))) hen macro in GOO.

pattern	<pre> = (,@qq-forms) </pre>	\mathcal{L}
СТ	(CT ,@body)	S
	EQ ,@body) at compile-time allowing a user to make avai s for the purpose of macro-expansion.	lable
CT-ALSO	(CT-ALSO ,@body)	\mathcal{S}
ilar to (eval	ct, but also includes a copy of , @body in compiled images. -when (:compile-toplevel :execute)) in Common L alue of Ct-ALSO is undefined.	
MACRO-EXPAND	(MACRO-EXPAND ,form)	S
recursively e	xpands macros in expression ,form.	

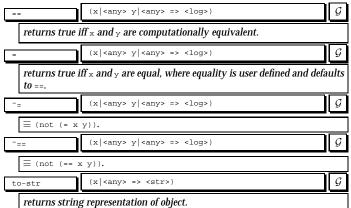

7 Scalars

 ${\cal GOO}$ provide a rich set of simple objects.

7.1 Any

All objects are derived from <any>.

<a< th=""><th>any></th><th>(<any>)</any></th><th>\mathcal{C}</th></a<>	any>	(<any>)</any>	\mathcal{C}
as	3	(x <any> y <any> => <any>)</any></any></any>	${\mathcal{G}}$
	coerces y to a	n instance of x.	
cl	lass-of	(x <any> => <class>)</class></any>	\mathcal{G}
	returns conci	rete class of x.	

7.2 Booleans

In \mathcal{GOO} , for convenience sake, true is often represented by anything that is not false, but $_{\#t}$ is reserved for the canonical true value. False is often used to represent null.

<log></log>	(<any>)</any>	\mathcal{C}
#f	<log></log>	\mathcal{I}
#t	<log></log>	\mathcal{I}
not	(x <any> => <log>)</log></any>	\mathcal{M}
\equiv (if x #f	x)	

7.3 Magnitudes

Magnitudes are totally orderable objects. Users are only required to implement < and =.

<mag></mag>	(<any>)</any>	\mathcal{C}
<	(x <mag> y <mag> => <log>)</log></mag></mag>	\mathcal{G}
returns iff $_{\times}$ i	is less than y.	
>	(x <mag> y <mag> => <log>)</log></mag></mag>	\mathcal{G}
\equiv (not (or	(< x y) (= x y))).	
<=	(x <mag> y <mag> => <log>)</log></mag></mag>	${\mathcal G}$
≡ (or (< x 3	y) (= x y)).	
>=	(x <mag> y <mag> => <log>)</log></mag></mag>	${\mathcal G}$
\equiv (not (< x	y)).	
min	(x <mag> y <mag> => <mag>)</mag></mag></mag>	${\mathcal G}$
returns the si	mallest of $_{\rm X}$ and $_{\rm Y}$.	
max	(x <mag> y <mag> => <mag>)</mag></mag></mag>	\mathcal{G}
returns the la	argest of $_{\rm X}$ and $_{\rm Y}$.	

7.4 Locatives

Locatives are word aligned pointers to memory. They are meant to be used to represent pointers to foreign data and not to point to interior \mathcal{GOO} object data.

<loc></loc>	(<mag>)</mag>	\mathcal{C}
loc-val	(x <loc> => <any>)</any></loc>	\mathcal{G}
returns the o	bject pointed to by x.	

 address-of
 (x | <any> => <loc>)
 G

 returns address of particular object.

7.5 Characters

GOO currently supports 8 bit ASCII characters.

<chr></chr>	(<mag>)</mag>
alpha?	(x <chr> => <log>)</log></chr>
returns true	e iff x is one of the ASCII upper or lowercase characters.
digit?	(x <chr> => <log>)</log></chr>
returns true	e iff x is one of the ten ASCII numeric characters.
lower?	(x <chr> => <log>)</log></chr>
returns true	e iff x is one of the ASCII lowercase characters.
upper?	(x <chr> => <log>)</log></chr>
returns true	e iff x is one of the ASCII uppercase characters.
to-digit	(x <chr> => <int>)</int></chr>
converts as	cii representation of digit to an integer one.
to-lower	(x <chr> => <chr>)</chr></chr>
returns low turns ×.	ercase version of uppercase alphabetic characters otherwise re-
to-upper	(x <chr> => <chr>)</chr></chr>
returns upp turns x.	vercase version of lowercase alphabetic characters otherwise re-

7.6 Numbers

<num></num>	(<mag>)</mag>	
+	(x <num> y <num> => <num>)</num></num></num>	
returns the	sum of its arguments.	
-	(x <num> y <num> => <num>)</num></num></num>	
returns the	difference of its arguments.	
*	(x <num> y <num> => <num>)</num></num></num>	
returns the	product of its arguments.	
/	(x <num> y <num> => <num>)</num></num></num>	
returns the	quotient of its arguments.	
	(x < num> => < int>)	
round		
returns clos implementa	sest integer to x . If x is exactly between two integers to tion is free to return either integer.	hen t
returns clos implementa round-to	<pre>est integer to x. If x is exactly between two integers to tion is free to return either integer. (x <num> n <int> => <flo>)</flo></int></num></pre>	hen t
returns clos implementa round-to	sest integer to x . If x is exactly between two integers to tion is free to return either integer.	hen t

div	(x <num> y <num> => <num>)</num></num></num>	\mathcal{G}	tanh (x <num> => <num>) G</num></num>
returns t	he trunc of the quotient of x and y .		
rem	(x <num> y <num> => <num>)</num></num></num>	G	
returns r	emainder after dividing $_{\times}$ by $_{Y}$.		7.6.1 Integers
pow	(x < num> e < num> => < num>)	G	GOO currently represents integers as 30 bit fixnums.
·	raised to the e power.		<int> (<num>) C</num></int>
<u> </u>	(x <num> => <num>)</num></num>	G	(x <int> y <int> => <int>) G</int></int></int>
sqrt		9	returns the logical inclusive or of its arguments.
	he square root of x.		& (x <int> y <int> => <int>)</int></int></int>
pos?	(x <num> => <log>)</log></num>	G	returns the logical and or of its arguments.
≡ (> x 0			^ ((x <int> y <int> => <int>))</int></int></int>
zero?	(x <num> => <log>)</log></num>	G	$\equiv ((\& x (~ y)) (\& (~ x) y))$
≡ (= x 0))		~ (x <int> => <int>) G</int></int>
neg?	(x <num> => <log>)</log></num>	${\mathcal G}$	returns the logical complement of its argument.
≡ (< x 0))		
neg	(x <num> => <num>)</num></num>	${\mathcal G}$	
≡ (- 0 x	ε)		returns true iff nth bit is 1.
abs	(x <num> => <num>)</num></num>	${\mathcal G}$	even? (x < int> => <log>)</log>
\equiv (if (n	neg? x) (neg x) x)		odd? (x <int> => <log>) G</log></int>
num-to-str- base	(x <num> b <int> => <str>)</str></int></num>	G	gcd (x <int> y <int> => <int>)</int></int></int>
returns s	tring representation of x in base b.		greatest common denominator.
num-to-str	(x <num> => <str>)</str></num>	G	lcm (x <int> y <int> => <int>)</int></int></int>
equiv (n	um-to-str-base x 10)		least common multiple.
str-to-num	(x <str> => <num>)</num></str>	G	<< (x <int> n <int> => <int>) G</int></int></int>
L	losest number corresponding to string x.		returns n bit shift left of x.
	(INCF ,name)	S	>> (x <int> n <int> => <int>) G</int></int></int>
INCF			returns signed n bit shift right of x.
\equiv (SET ,	<pre>name (+ ,name 1)) (INCF (,name ,@rest))</pre>	S	>>> (x <int> n <int> => <int>)</int></int></int>
			returns unsigned n bit shift right of x.

 $^{^1 \}mbox{When optimization is in place, the} \ :$ suffixed functions will be deprecated.

8.2 Enumerators

Enumerations are the foundation of collections and are designed to provide the convenience of Lisp's list interface (e.g., null, car, cdr) for all collections. In defining a new collection class, a user must implement at minimum an enumerator class and the enumeration protocol: enum, fin?, nxt, and now. For efficiency, users might choose to override more methods such as len, elt, elt-setter, etc. Enumeration behavior is undefined if an enumerator is modified during enumeration.

<enum></enum>	(<any>)</any>	\mathcal{C}	
enum	(x <col/> => <enum>)</enum>	\mathcal{G}	
returns init	ial enum for iterating over x.		
fin?	(x <enum> => <log>)</log></enum>	\mathcal{G}	
returns true	iff no more elements exist from given enum x.		
nxt	(x <enum> => <enum>)</enum></enum>	\mathcal{G}	
returns enu	m pointing to next element in enum x.		
now	(x <enum> => <any>)</any></enum>	\mathcal{G}	
returns current element given enum ×.			
now-setter	(v x <enum>)</enum>	${\mathcal G}$	
sets current	element given enum x to v.		
now-key	(x <enum> => <any>)</any></enum>	\mathcal{G}	
returns curi	rent key given enum ×.		
FOR	(FOR (,for-clause) ,@body)	\mathcal{S}	
parallel iteration over collections using enumerations.			
where			
,for-clause	\equiv (,var ,col) ((tup ,keyvar ,var) ,col)	\mathcal{L}	
specifies one parallel iteration over a collection , col binding successive values to , var and optionally keys to , keyvar.			

8.3 Packers

Packers are the complement of enumerators and are the imperative version of $_{\tt fold}.$ The default packer returns a list of all accumulated values:

They can also be used for summing values etc:

	(1 2 3 4 5))) dd? e) (pack-in x e)))		
<packer> (<an< td=""><td>y>)</td><td>\mathcal{C}</td></an<></packer>	y>)	\mathcal{C}	
packer-add (p <	packer> x => <packer>)</packer>	\mathcal{G}	
returns a copy pack	er $_{P}$ augmented with element $_{x}$.		
packer-res (p <	packer> => <any>)</any>	\mathcal{G}	
returns result of pa	ckings over p.		
packer (ini	t add <fun> res <fun>)</fun></fun>	\mathcal{G}	
returns a simple packer that starts its value out with init, is augmented with add, and whose final value is computed with res.			
packer-fab (t <	type> => <packer>)</packer>	\mathcal{G}	
returns a new type	t specific packer.		

<pre>packer-fab (t (t< <seq>) => <packer>)</packer></seq></pre>	\mathcal{M}
\equiv (packer '() pair (op as t (rev! .)))	
packer-fab (t (t= <int>) => <packer>)</packer></int>	\mathcal{M}
= (packer 0 + (op .))	
PACKING-WITH ((,var ,pack)) ,@body)	S
mechanism for packing objects using given packer into , var.	
PACKING-IN (PACKING-IN (,name ' ',type) ,@body)	S
\equiv (PACKING-WITH (,name (packer-fab ,type)) ,@body).	
(PACKING-IN (,name) ,@body)	S
\equiv (PACKING-IN (,name ' ' <lst>) ,@body).</lst>	
PACKING (PACKING ,@body)	S
\equiv (PACKING-IN (packer-) ,@body (packed packer-)).	
PACK-IN (PACK-IN ,pack ,x)	S
folds , x into packer in , pack.	
PACK (PACK ,x)	S
<pre> Ξ (PACK packer- ,name). </pre>	
PACKED (PACKED , name)	S
\equiv (packer-res ,name).	

8.4 Maps

Maps represent collections with explicit keys.

 (<col>)
 (<map> <col!>)
 (<map> <col!>)

<tab></tab>	(
	ear constant-time aggregate data structures. Users can define bles by subclassing and overriding the key-test and tab-hash			
tab-growth- factor	(x <tab> => <flo>)</flo></tab>			
factor by wh	ich to grow capacity.			
tab-growth- threshold	(x <tab> => <flo>)</flo></tab>			
when to grow	w based on proportion of total table capacity.			
tab-shrink- threshold	(x <tab> => <flo>)</flo></tab>			
when to shri	nk based on proportion of total table capacity.			
tab-hash	(x <tab> => <fun>)</fun></tab>			
returns hash function.				
id-hash	(x <tab> => <int>)</int></tab>			
hash functio	n based on identity.			

С

C

8.5 Sequences

Sequences are collections with nonnegative integer keys.

<seq></seq>	(<col/>)	\mathcal{C}
<seq.></seq.>	(<seq> <col.>)</col.></seq>	\mathcal{C}
immutable s	requence.	
lst	(x <seq> => <any>)</any></seq>	\mathcal{G}
\equiv (elt x 0)		
2nd	(x <seq> => <any>)</any></seq>	\mathcal{G}

Ξ (elt x 1)		returns seq	uence with n concatenated copies of x .	
3rd (x <seq> => <any>)</any></seq>	${\mathcal G}$	split	(x <seq> sep => <seq>)</seq></seq>	\mathcal{G}
\equiv (elt x 2)		returns seq	uence of subsequences of x separated by sep.	<u> </u>
last (x <seq> => <any>)</any></seq>	${\mathcal G}$	join	(xs <seq> sep <seq> => <seq>)</seq></seq></seq>	\mathcal{G}
<pre></pre>		returns seq	uence composed of sequences in xs joined with sep .	
pos (x <seq> v <any> => (t? <int>))</int></any></seq>	${\mathcal G}$			
finds position of ∇ in x else returns false.				
finds $(x \langle seq \rangle \langle seq \rangle \Rightarrow (t? \langle int \rangle))$	${\mathcal G}$	8.5.1 Muta	ble Sequences	
finds position of $_{\rm Y}$ in $_{\rm x}$ else returns false.		<seq!></seq!>	(<seq> <col!>)</col!></seq>	\mathcal{C}
add $(x < seq > y < any > = > < seq >)$	\mathcal{M}	rev!	(x <seq!> => <seq!>)</seq!></seq!>	${\mathcal G}$
returns sequence with $_{\rm Y}$ added to the end of $_{\rm X}.$		returns des	tructively reversed sequence.	
push (x <seq> y <any> => <seq>)</seq></any></seq>	${\mathcal G}$	cat!	(x <seq!> more => <seq!>)</seq!></seq!>	\mathcal{G}
returns sequence with $_{\rm Y}$ added to $_{\rm X}$.		returns des	tructively concatenated sequences.	
<pre>pop (x <seq> => (tup <any> <seq>))</seq></any></seq></pre>	G	add!	(x <seq!> y <any> => <seq!>)</seq!></any></seq!>	\mathcal{G}
returns last pushed element of x and new sequence with that e	element re-	returns col	lection with $_{\rm Y}$ added to the end of $_{\rm X}$.	
moved from x.		push!	(x <seq!> y <any> => <seq!>)</seq!></any></seq!>	\mathcal{G}
rev (x <seq> => <seq>)</seq></seq>	G	returns col	lection with $_{\rm Y}$ added to the front of $_{\rm X}$.	
returns reversed sequence.		pop!	<pre>(x <seq!> => (tup val <any> <seq!>))</seq!></any></seq!></pre>	G
cat (x <seq> more => <seq>)</seq></seq>	${\mathcal G}$	pops eleme	nt from front of sequence.	
returns concatenated sequences.		PUSHF	(PUSHF,place,val)	S
<pre>sub (x <seq> from <int> below <int> => <seq>)</seq></int></int></seq></pre>	${\mathcal G}$		1 onto the sequence stored in ,place, updates ,place to	contain
subsequence of x between from and below.			quence, and returns the new sequence.	
'[' ']' '[' ,x ,from ,below ']'	S	POPF	(POPF ,place)	S
\equiv (sub ,x ,from ,below)			te from the sequence stored in ,place, replaces the sequent sequence, and returns the value.	nce with
<pre>sub* (x <seq> from <int> => <seq>)</seq></int></seq></pre>	${\mathcal G}$		(x <seq!> v <any> i <int> => <seq!>)</seq!></int></any></seq!>	G
\equiv (sub x from (len x))		ins!		9
'[' ']' '[',x,from * ']'	S	inserts v be	_ [
E (sub* ,x ,from)		sub-setter	(dst <seq!> src <seq> from <int> below <int>)</int></int></seq></seq!>	G
ins (x <seq> val i <int> => <seq>)</seq></int></seq>	G		bsequence in range between from and below of dst with over the ove	
returns copy of x's with val inserted before i.		one.		
del-dups (x <seq> => <seq>)</seq></seq>	G	sub*-setter	(dst <seq!> src <seq> from <int>)</int></seq></seq!>	${\mathcal G}$
returns sequence with all duplicates removed.		\equiv (sub-set	tter dst src from (len dst))	
del-vals (s <seq> val => <seq>)</seq></seq>	${\mathcal G}$	del-vals!	(x <seq!> v <any> => <seq!>)</seq!></any></seq!>	${\mathcal G}$
returns sequence with all copies of val removed.		removes al	v's from x.	
sort-by (s <seq> f <fun> => <seq>)</seq></fun></seq>	G	del-dups!	(x <seq!> => <seq!>)</seq!></seq!>	${\mathcal G}$
returns a sorted copy of ${\tt s}$ using ${\tt f}$ as a comparator.		removes all	duplicates from x.	
sort (s <seq> => <seq>)</seq></seq>	G	sort-by!	(s <seq> f <fun> => <seq>)</seq></fun></seq>	${\mathcal G}$
≡ (sort-by s <)		destructive	ly sorts B using f as a comparator.	
pick (f <fun> x <seq> => <seq>)</seq></seq></fun>	\mathcal{G}	sort!	(s <seq> => <seq>)</seq></seq>	\mathcal{G}
returns new sequence with elements corresponding to non-fa when calling predicate f.	lse results	≡ (sort-by	r! s <)	
prefix? (x <seq> prefix <seq> => <log>)</log></seq></seq>	G			
returns true iff sequence x starts with sequence prefix.		8.5.2 Lists		
<pre>suffix? (x <seq> suffix <seq> => <log>)</log></seq></seq></pre>	G	Lists are alw	ays "proper" lists, that is, the tail of a list is al	ways a
returns true iff sequence x ends with sequence suffix.		list. Lists mig	ght be deprecated in future releases of \mathcal{GOO} .	
repeat (x <seq> n <int> => <seq>)</seq></int></seq>	G	<lst></lst>	(<seq!>)</seq!>	C
	لتاه	<list></list>	<lst></lst>	\mathcal{A}

head	(x <lst> => <any>)</any></lst>			
tail	(x <lst> => <lst>)</lst></lst>			
lst	(elts => <lst>)</lst>			
returns list of arguments.				
list	lst A			
nil	<lst> I</lst>			
aka ().				
pair	(x <any> y <lst> => <lst>)</lst></lst></any>			
returns new list with x as head and y as tail.				

8.5.3 Zips

A zip is a sequence of tuples of sucessive elements of sequences. A zip has the length of its shortest constituent sequence.

<zip></zip>	(<seq.>)</seq.>		
zip	(cs (<seq>) => <zip>)</zip></seq>		
returns a zip	over sequences cs.		
unzip	(z <zip> => <tup>)</tup></zip>		
returns a tuple of z's constituent sequences.			

8.5.4 Flat Sequences

Flats represents sequences with constant access time. Flat enum provides an enum implementation of all but $_{\tt now}$ and $_{\tt now-setter}.$

<flat></flat>	(<seq>) C</seq>			
<flat-enum></flat-enum>	(<enum>) C</enum>			
<tup></tup>	(<flat> <seq.>)</seq.></flat>			
Tuples are i GOO.	mmutable flat sequences and represents multiple values in			
tup	(elts => <tup>)</tup>			
creates a tuple with elements being elts.				
<vec></vec>	(<flat> <seq!>)</seq!></flat>			
Stretchy vectors resize when needed.				
vec	(elts => <sec>)</sec>			
returns new	vector with elements elts.			

Strings

\mathcal{GOO} currently implements ASCII strings.

<str></str>	(<flat> <mag> <seq.>)</seq.></mag></flat>	\mathcal{C}
str	(elts => <str>)</str>	\mathcal{G}
returns new	string with elements elts.	
case- insensitive- string-hash	(x <tab> => (tup hash <any> gc-state <any>))</any></any></tab>	G
case- insensitive- string-equal	(x <str> y <str> => <log>)</log></str></str>	G

8.6 Lazy Series'

Represents an immutable sequence of numbers specified using a start number from, a step amount by, and an inclusive bound to.

		· · · ·			
<1	range>	(<seq.>)</seq.>	\mathcal{C}		
		(from <num> test <fun> lim <num> by <fun></fun></num></fun></num>			
ra	ange-by	=> <range>)</range>	\mathcal{G}		
	returns a ran x lim) is fals	ge starting from, updated with by , and continuing until (test		
ra	ange	<pre>(from <num> test <fun> lim <fun> => <range>)</range></fun></fun></num></pre>	\mathcal{G}		
	\equiv (range-by	<pre>from test lim (op + _ 1))</pre>			
fı	rom	(from <num> => <range>)</range></num>	\mathcal{G}		
	\equiv (range from	om (always #t) 0)			
be	elow	(lim <num> => <range>)</range></num>	\mathcal{G}		
	\equiv (range 0 +	< lim)			
< 5	step>	(<seq.>)</seq.>	\mathcal{C}		
	Steps represent step functions.				
f	irst-then	(first <fun> then <fun> => <step>)</step></fun></fun>	\mathcal{G}		
	returns a new step object, calling thunks first to retrieve initial value and then to retrieve subsequent values.				
ea	ach	(f <fun> => <each>)</each></fun>	\mathcal{G}		
	returns a nev	v each object, calling £ thunk to retrieve each value.			
<0	cycle>	(<seq.>)</seq.>	С		
Cycles provide a mechanism to create infinite sequences repeating a certain sequence over and over again.					
C)	ycle	(x => <cycle>)</cycle>	\mathcal{G}		
	returns a cycles that repeats elements of x.				

9 Symbols

Symbols are uniquified (aka interned) strings.

<sym></sym>	(<any>)</any>	\mathcal{C}		
<sym-tab></sym-tab>	(<tab>)</tab>	\mathcal{C}		
symbol table	class.			
as	(_ (t= <sym>) x <str> => <sym>)</sym></str></sym>	\mathcal{M}		
coerces a stri	ng to a symbol.			
cat-sym	(elts => <sym>)</sym>	\mathcal{G}		
returns a symbol formed by concatenating the string representations of elts.				
gensym	(=> <sym>)</sym>	\mathcal{G}		
returns a system specific unique symbol.				
fab-setter- name	(x <sym> => <sym>)</sym></sym>	\mathcal{G}		
≡ (as <sym></sym>	(cat (as <str> x) "-setter")).</str>			

10 Conditions

Conditions are objects representing exceptional situations. \mathcal{GOO} provides restartable conditions as well as the more traditional stack unwinding conditions. A condition is an object used to provide information to a handler. A handler is an object with a handler function used to take care of conditions of a particular type.

Signalling is a mechanism for finding the most appropriate handler for a given condition. See DRM [4] for more information.

<condition></condition>	(<any>)</any>	\mathcal{C}
default- handler	(x <condition> => <fun>)</fun></condition>	\mathcal{G}
called if no a	appropriate handler is in force.	
default- handler-		
description	(c <condition> => <str>)</str></condition>	G
	ng describing an anonymous handler for this type of condi	tion.
build- condition- interactively	(type < condition> in out => < condition>)	${\mathcal G}$
to fill in any	condition of the specified type and interactively prompt the v important props. Called by the debugger. Methods should to build the condition, then set the props for their own cla	call
sig	(x <condition> args)</condition>	${\mathcal G}$
signals a cor	ndition with optional arguments args.	
<simple- condition></simple- 	(<condition>)</condition>	\mathcal{C}
a condition of	consisting of a msg message and arguments.	
condition- message	(x <simple-condition> => <str>)</str></simple-condition>	\mathcal{P}
<i>returns</i> msg s	string.	
condition- arguments	(x <simple-condition> => <lst>)</lst></simple-condition>	\mathcal{P}
returns msg s	string arguments.	
<pre><serious- condition=""></serious-></pre>	(<condition>)</condition>	\mathcal{C}
a condition t	that can not be safely ignored.	
<error></error>	(<serious-condition>)</serious-condition>	\mathcal{C}
a condition t	that indicates something is invalid about the program.	
error	(x <any> args)</any>	\mathcal{G}
signals an ei	rror.	
error	(x <str> args)</str>	\mathcal{M}
signals a sin	nple error.	
<simple- error></simple- 	(<error> <simple-condition>)</simple-condition></error>	\mathcal{C}
an error that	t consists of a mag message and arguments.	
<restart></restart>	(<condition>)</condition>	\mathcal{C}
used for rest	arting a computation.	
<handler></handler>	(<any>)</any>	С
	for handling a signaled condition.	
handler- function	(x <handler> => <fun>)</fun></handler>	\mathcal{G}
fab-handler	(x <fun> => <handler>)</handler></fun>	${\mathcal G}$
creates a har	ndler from a handler function.	
handler- matches?	<pre>(x <handler> y <condition> => <log>)</log></condition></handler></pre>	\mathcal{G}
matches?	(x <handler> y <condition> => <log>) determining whether a handler handles a particular condit</log></condition></handler>	

installs ,handler as a condition handler for the duration of (SEQ ,@body), using the instructions provided by ,try-options. ,try-options should either be the name of the condition type to handle, or a ,try-option-list with zero or more of the following options:

- (TYPE , expr) => An expression returning the type of condition to handle.
- (TEST , @body) => Code which returns #t if the condition is applicable, and #f otherwise. This may be called at arbitrary times by the runtime, so it shouldn't do anything too alarming.
- (DESCRIPTION , message , @arguments) => A human-readable description of this handler. Used by the debugger.

The handler function should take two arguments: the <code>,condition</code> to be handled, and a <code>,resume</code> function. if a matching condition is signaled then the handler function is called with the signaled condition and a resume function to be called if the handler wants to return a value to be used as the result of the signaling sig call. the handler has three possibilities: (1) it can handle the condition by taking an exit using ESC, (2) it can resume to the original Sig call using the resume function called with the value to be returned, or (3) it can do neither, that is, it can choose not to handle the condition by just falling through to the end of the handler (cf. Dylan's BLOCK/EXCEPTION and LET HANDLER) and the next available handler will be invoked. Note that \mathcal{GOO} does not unwind the stack before calling handlers!

11.1.2 String Ports

String ports provide port interface mapped onto strings.

os-name

(=> <str>)

returns name of current operating-system.

 \mathcal{M}

os-val	(s <str> => <str>)</str></str>	\mathcal{M}
returns OS e	environment variable value.	
os-val- setter	(v <str> s <str> => <str>)</str></str></str>	\mathcal{M}
sets OS envi	ironment variable value.	
sets OS envi	(=> <int>)</int>	

12.1 Files and Directories

A preliminary set of file and directory facilities are provided.

file-mtime	(filename <str> => <flo>)</flo></str>
	ast modification time of a file in seconds (relative to the n as a floating point number.
file-exists?	(filename <str> => <log>)</log></str>
return true i name.	f and only if a file (or a directory, etc.) exists with the given
file-type	(filename <str> => <sym>)</sym></str>
<i>return 'file the file.</i>	, 'directory or some other symbol, depending on the type of
create- directory	(filename <str> => <sym>)</sym></str>
	ctory with the given name. The parent directory must already ust contain no item with the given name.
parent- directory	(name <str> => <str>)</str></str>
find the paren	nt directory of the current filename.
probe- directory	(name <str> => <str>)</str></str>
make sure th	at the named directory exists.

12.2 Pathnames

Pathnames allow you to work with hierarchical, structured pathnames in a reasonably portable fashion.

pathname-to- components	(pathname <str> => <lst>)</lst></str>
special value • root • up -> (• curren Volume labe stored in a s	name, split it into a list of individual directories, etc. Three is are returned as symbols: → This path starts in the root directory Go up a directory t → Remain in the current directory ds, drive letters, and other non-path information should be single tagged list at the head. Note that the hierarchical por- bathname (everything but the label) must be non-empty at all
components- to-pathname	(components <lst> => <str>)</str></lst>
reassemble c	omponents created by the above function.
label- components	(components <lst> => <lst>)</lst></lst>
get any leadi	ing directory label.
hierarchical- components	(components <lst> => <lst>)</lst></lst>
get rid of any	y leading directory label, etc.
components- last	(components <lst> => <any>)</any></lst>
return the la	st item in a list of components.

components- basename	(components <lst> => <lst>)</lst></lst>
handle cases you are even	It the last item of a bunch of components. Do some magic to like 'foo.txt' => './' If you call this function enough times, itually guaranteed to get components list ending in root, up or nuires the last item to be a string.
components- parent- directory	(components <lst> => <lst>)</lst></lst>
calculate the	parent directory of a pathname.

13 Threads

Threads allow for expressing concurrent programs. The assumed model is shared memory with explicit synchronization and symmetric multiprocessing and is based heavily upon pthreads This section is preliminary and might change in the future. There are several limitations in the current implementation. It represents a rudimentary but usable subset of typical thread operations. Tables and vectors require user locks to ensure thread safety and no out of language crashes. Finally, the compiler, interpreter, and (re)definition machinery are thread unsafe and can only reliably be run in one thread.

<thread></thread>	(<any>)</any>	C
	thread of executation schedulable across multiple proces n executes thread-function in separate thread.	sors.
thread-name	(thread < thread > => (t? < sym>))	\mathcal{P}
thread- priority	(thread <thread> => <int>)</int></thread>	\mathcal{P}
thread- function	(thread <thread> => <fun>)</fun></thread>	\mathcal{P}
new	<pre>(x (t< <thread>) inits => <thread>)</thread></thread></pre>	\mathcal{M}
Creates threa OS thread.	d and runs thread-function of created thread in sep	arate
SPAWN	(SPAWN ,@body)	S
\equiv (FAB <thr< td=""><td>ead> thread-function (fun () ,@body))</td><td></td></thr<>	ead> thread-function (fun () ,@body))	
thread-yield	()	\mathcal{M}
Surrenders p	rocessor to another thread.	-
thread-join	(thread <thread>)</thread>	\mathcal{M}
Causes curre	nt thread to wait for the termination of thread.	
thread- current	(=> <thread>)</thread>	\mathcal{M}
all-threads	(=> <tup>)</tup>	\mathcal{M}
sleep	(secs <flo>)</flo>	\mathcal{M}
Pauses curre	nt thread for secs seconds.	
<lock></lock>	(<any>)</any>	\mathcal{C}
Represents a	mutex.	
lock-name	(lock <lock> => (t? <sym>))</sym></lock>	\mathcal{P}
new	(x (t< <lock>) inits => <lock>)</lock></lock>	\mathcal{M}
lock-lock	(lock <lock>)</lock>	\mathcal{M}
Obtain exclu	sive access to lock waiting if necessary.	
lock-unlock	(lock <lock>)</lock>	\mathcal{M}
Free up exclu	sive access to lock potentially allowing another thread ac	cess.
WITH-LOCK	(WITH-LOCK ,lock ,@body)	S

\equiv (FIN (SEQ	<pre>(lock-lock ,lock) ,@body) (lock-unlock ,lock))</pre>	
<event></event>	(<any>)</any>	\mathcal{C}
Represents a	condition variable used for interthread notification.	
event-name	(event <event> => (t? <sym>))</sym></event>	\mathcal{P}
new	(x (t< <event>) inits => <event>)</event></event>	\mathcal{M}
event-signal	(event <event> lock <lock>)</lock></event>	\mathcal{M}
Unblocks at 1	least one thread waiting on event.	
event- broadcast	(event <event> lock <lock>)</lock></event>	\mathcal{M}
Unblocks all	threads waiting on event.	
event-wait	(event <event> lock <lock> => <log>)</log></lock></event>	\mathcal{M}

14 Compiler

 \mathcal{GOO} 's compiler, g2c, compiles \mathcal{GOO} source code to C. It lives within the eval module. During a given session, g2c recompiles only used modules that are either modified or use modified modules.

<g2c-module- loader></g2c-module- 	(<module-loader>)</module-loader>
a g2c module	e loader used in g2c builds.
g2c-def-app	(appname <str> modname <str> => <g2c-module-loader>)</g2c-module-loader></str></str>
constructs a	g2c module loader to be used in future g2c builds.
g2c-build- app	(loader <g2c-module-loader>)</g2c-module-loader>
	OO app into C in subdirectory of GOO 's toplevel C directory loader's top modname.
g2c-goo	() M
builds entire	goo world.
g2c-test	(name)

15 Top Level

Functions which load code at runtime require a symbol specifying the module name to use.

the module hame to use.				
load	$(\texttt{filename} < \texttt{str} > \texttt{modname} < \texttt{sym} > = > <\texttt{any} >) \qquad $			
returns the result of evaluating the result of reading file named filename into module modname.				
eval	(x < any > modname < sym > => < any >)			
return's result of evaluating x.				
top	(modname <sym>)</sym>			
runs top-level read-eval-print loop which reads from in and writes to out.				
runs top-level	read-eval-print loop which reads from in and writes to out.			
runs top-level	read-eval-print loop which reads from in and writes to out.			
save-image	- -			
save-image	(filename <str>)</str>			

16 Installation

Unpack a \mathcal{GOO} development or platform specific binary tarball into an appropriate staging directory. In the case of a binary tarball, there will be five directories: doc, bin, c, src, and emacs. You can just run \mathcal{GOO} from the bin subdirectory.

In the case of a development tarball, you must install it. After unpacking, there will be five directories: doc, bin, c, src, and emacs. On windows, installation must be conducted from within a cygwin shell. \mathcal{GOO} requires Boehm's GC to be installed as a shared library on linux or under the source dir GOO_DIR/gc downloadable from http://www.hpl.hp.com/personal/Hans.Boehm/gc/gc_source/gc.tar.gz.

Generate makefiles by executing ./configure. Configure takes a -prefix argument which sets the installation root, GOO_ROOT. Normally GOO_ROOT is set to /usr/local but can be set to staging directory for a personal installation. Configure also takes a --with-threads argument which enables threads support on linux. The rest of the configure arguments can be found by executing ./configure --help. Execute make to build \mathcal{GOO} and make install to install it. Executing make install will build \mathcal{GOO} with the proper roots, creating lib and mods directories, and installing \mathcal{GOO} in bin and setting up doc. On windows, it is necessary to add GOO_BIN to your PATH.

You can override the default GOO_ROOT by setting up your os environment variable. For example, my GOO_ROOT on linux is: setenv GOO_ROOT /home/ai/jrb/goo. Environment variable setting depends on the shell you're using. In order to run g2c-goo you need to set GOO_BUILD_ROOT to the directory which includes the src directory. During start up, \mathcal{GOO} will load two patch files:

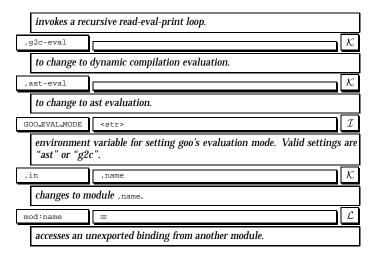

\${GOO_ROOT}/init.goo
\${HOME}/.goo/init.goo

You can customize your \mathcal{GOO} by adding forms to these files.

17 Usage

Typing g_{00} at your shell will start up a \mathcal{GOO} read-eval-print loop, which accepts sexpressions and top-level commands commencing with a comma. The following is a list of available commands:

,quit]	<i>K</i>
exits from \mathcal{G}	300.	
C-c]	<i>K</i>

17.1 Development

To batch compile \mathcal{GOO} to C:

goo/user 0<= (use eval/g2c)
goo/user 0=> #f
goo/user 0<= (g2c-goo)</pre>

To then compile the C:

cd \${GOO_ROOT}/c make

To run the test suites:

goo/user 0<= (use tests)
goo/user 0=> #f
goo/user 0<= (run-all-tests)</pre>

17.2 Debugger

A keyboard interrupt or any error enters the user into the debugger which provides a superset of the commands available at toplevel. The following are debugger specific commands:

,up		\mathcal{K}		
goes up one level.				
,top		\mathcal{K}		
goes to top le	goes to top level.			
,restarts		\mathcal{K}		
lists available restarts				
,restart	, n	\mathcal{K}		
chooses available restart.				
,handlers	, n	\mathcal{K}		
shows available handlers.				
,backtrace		\mathcal{K}		
prints out called functions and their arguments.				
,bt		\mathcal{K}		
prints out called functions.				
,frame	,n	\mathcal{K}		
prints out nth called function and its arguments.				
,frame-var	,n ,name	\mathcal{K}		
prints out nth called function's parameter name.				
frame-var	(n <int> name <sym>)</sym></int>	\mathcal{F}		

returns nth called function's parameter name.

17.3 Emacs Support

A rudimentary emacs-based development system is provided.

17.3.1 Emacs Mode

Put $_{\tt emacs/goo.el}$ in your emacs lisp directory. Add the following to your $_{\tt emacs}$ file:

(autoload 'goo-mode "goo" "Major mode for editing Goo source." t) (setq auto-mode-alist (cons '("\\.goo\\'" . goo-mode) auto-mode-alist))

Useful features include the following. You can add "font-lock" mode by adding <code>(global-font-lock-mode t)</code> to your <code>.emacs</code>: In a given buffer, you can toggle font-lock with <code>M-x font-lock-mode</code>. Finally, check out the "Index" menu item in a \mathcal{GOO} buffer for other options.

For even more fun, load $_{macs/goo-font-lock.el}$ for a color coded parenthesis nesting aid ².

17.3.2 Emacs Shell

Put <code>emacs/goo-shell.el</code> in your emacs lisp directory. Add the following to your <code>.emacs:</code>

make sure to set up the goo-program-name to correspond to your installation area.

Useful command / key-bindings are:

```
M-C-x goo-send-definition
C-c C-e goo-send-definition
```

- C-c M-e goo-send-definition-and-go
- C-c C-r goo-send-region
- C-c M-r goo-send-region-and-go C-c C-z switch-to-goo

C-c C-z switch-to-goo

Check out $_{\tt goo-shell.el}$ for the complete list of command / keybindings. I doubt the compile commands do anything useful cause there isn't a compiler.

17.3.3 TAGS

Emacs TAGS files can be generated by typing make all-tags in the src directory. Useful tags commands / key-bindings are:

M-. find-tag M-, tags-loop-continue tags-search tags-query-replace

18 Caveats

This is the first release of \mathcal{GOO} . \mathcal{GOO} is relatively slow at this point. There are no compiler optimizations in place. The error reporting is minimal and no source locations are tracked. Also hygiene is not implemented and there are some potential hygiene leaks. Dynamic compilation and image saving work only on Linux.

This manual is preliminary. Please consult the runtime libraries in the $_{\tt src}$ directory. Also check out Scheme and Dylan's manuals for

²The original idea was dreamed up and first implemented by Andrew Sutherland and then improved by James Knight.

information on their lexical structure and special form behavior respectively.

Please, please, please send bug reports to <code>jrb@googoogaga.org</code>. I will fix your bugs asap. The \mathcal{GOO} website <code>www.googoogaga.org</code> will have papers, releases, FAQS, etc.

19 Future

The plan is for \mathcal{GOO} to evolve in a number of dimensions. First of all, \mathcal{GOO} 's design is incomplete. Parameter lists and dispatch will be improved to allow methods of differing numbers of required parameters and named parameters. Lisp lists will most likely be deprecated and program fragments will be represented by a richer data structure which can capture source locations and hygiene information. This will be accomplished with minimal impact on macro definitions and WYSIWYG program construction and destructuring facilities. The module system will be improved to include in the very least renaming and selective imports. Finally, \mathcal{GOO} will support a more complete loopless programming protocol inspired by Waters' series [5].

Secondly, the overall mission is to crank the implementation until its performance is competitive with Java while at the same time maintaining low-latency interactivity. The basic approach involves incremental whole program optimization using simple dynamic compilation combined with partial evaluation. One important optimization will be side effect analysis combined with a generalized box/unbox optimization to remove unnecessary creation of immutable enumerators and packers for instance. Similar analyses and optimizations will be employed to optimize loopless programming patterns involving map and fold.

20 History and Acknowledgements

GOO has greatly benefitted from the help of others. During the winter of 2001, I briefly discussed the early design of Proto, a Prototype-based precursor to \mathcal{GOO} , with Paul Graham and his feedback was very useful. From there, I bootstrapped the first version of Proto for a seminar, called Advanced Topics in Dynamic Object-Oriented Language Design and Compilation (6.894), that I cotaught with Greg Sullivan and Kostas Arkoudas. The 6.894 students were very patient and gave me many helpful suggestions that greatly improved Proto. During and after the seminar, Greg Sullivan reviewed many ideas and helped tremendously, including by writing the Emacs goo-mode. James Knight was one of the 6.894 students and became my MEng student after the course. He has helped in many many ways including the writing of the save-image facility, the speeding up of the runtime, and the improving of the non local exit facility. Eric Kidd worked with me during the summer of 2001 implementing the module system, restarts, and the dependency tracking system. During that summer I decided that a Prototype-based object system was inadequate for the type system I was interested in supporting and changed over to the present type-based system. I presented my ideas on Proto at LL1 in the Fall of 2001. Many stimulating conversations on the follow on LL1 discussion list inpired me. In fact, during the course of defending Proto's form of object-orientation on that list I came up with its current name, \mathcal{GOO} , and it stuck. And rew Sutherland became my MEng student in the winter of 2002, wrote a \mathcal{GOO} SWIG [2] backend, and has provided useful feedback on \mathcal{GOO} 's design. I also wish to thank Boehm, Demers, and Weiser for writing the conservative GC upon which this initial version of \mathcal{GOO} is based. Finally, I would like to thank Keith Playford for his continued guidance in language design and implementation and for his ever present and rare sense of good taste.

A Class Precedence List

This section defines the algorithm for computing a class's linearized ancesters from its parents, its parent's parents, etc. \mathcal{GOO} uses the C3 class linearization rule [1]. The following is the \mathcal{GOO} implementation of this algorithm:

```
(dm class-ordered-ancestors (c|<class> => <lst>)
  (def parents (class-parents c))
  (rep merge-lists
      ((partial-cpl <lst>
         (lst c))
       (remaining-lists|<lst>
         (add (map class-ancestors parents) parents)))
    (if
       (all? empty? remaining-lists)
        (rev! partial-cpl)
        (loc ((candidate (c)
                (loc ((tail? (1|<lst>) (mem? (tail 1) c)))
              (and (not (any? tail? remaining-lists)) c)))
(candidate-at-head (1|<lst>)
                (and (not (empty? 1)) (candidate (head 1)))))
          (def next (any? candidate-at-head remaining-lists))
          (if next
              (loc ((del-next (1 <lst>)
                      (if (== (head 1) next) (tail 1) 1)))
                (merge-lists
                  (pair next partial-cpl)
                  (map del-next remaining-lists)))
              (error "inconsistent precedence graph")))))))
```

B Subtyping Rules

This section defines the subtyping rules for \mathcal{GOO} in terms of sub-type methods.

```
(dm subtype? (t1|<union> t2|<type> => <log>)
  (all? (op subtype? _ t2) (type-elts t1)))
(dm subtype? (t1|<type> t2|<union> => <log>)
  (any? (op subtype? t1 _)) (type-elts t2)))
(dm subtype? (t1|<union> t2|<union> => <log>)
  (all? (op subtype? _ t2)) (type-elts t1)))
(dm subtype? (t1|<class> t2|<class> => <log>)
  (subclass? t1 t2))
(dm subtype? (t1|<singleton> t2|<class> => <log>)
  (subclass? t1 t2))
(dm subtype? (t1|<subclass> t2|<class> => <log>)
  (subclass? <class> t2)|(class> => <log>) (subclass? <class> t2|<class> => <log>) #f)
(dm subtype? (t1|<singleton> t2|<singleton> => <log>) #f)
(dm subtype? (t1|<slass> t2|<singleton> => <log>) #f)
(dm subtype? (t1|<subclass> t2|<singleton> => <log>) #f)
```

(and (== t1 <class)) (== (type-class t2) <class>))) (dm subtype? (t1|<subclass> t2|<subclass> => <log>) (subclass? (type-class t1) (type-class t2))) (dm subtype? (t1|<singleton> t2|<subclass> => <log>) (and (isa? (type-object t1) <class>) (subclass? (type-object t1) (type-class t2)))) (dm subtype? (t1|<product> t2|<type> => <log>) #f) (dm subtype? (t1|<product> t2|<product> => <log>) #f) (dm subtype? (t1|<product> t2|<product> => <log>) #f) (and (== (len (type-elts t1)) (len (type-elts t2)))) (all? (zipped subtype?) (zip (type-elts t1) (type-elts t2))))) (dm subtype? (t1|<product> t2|<class> => <log>) (subtype? <tup> t2))
