 From: T. H. Van Vleck  
 Date: June 17, 1976  
 Subject: New Storage System Long Range Plans (revised)

This document reports changes since MTR-119.

OVERVIEW

The following table shows the major phases of the implementation of the new storage system.

Phase	Date
I Command Level One user at command level	May 75
II Prototype Running Several users	June 75
III Design Review Error recovery, backup, mount/demount	Oct 75
IV Installable System Run mini-service at CISL	Nov 75
V Initial Installation at MIT No mount/demount	Feb 76
VI Follow-up Installation at MIT Operational enhancements	March 76
VII MR 4.0 Installed at MIT With mount/demount	May 76
VIII Release MR 4.0	June 76
IX Further Enhancements Administrative improvements	-

---

Multics Project internal working documentation. Not to be reproduced or distributed outside the Multics Project.

CHANGES SINCE LAST REPORT

Since MTR-119 was published, the following events have occurred:

1. Systems 28-1 through 28-8 have been installed at MIT and Phoenix, completing the capabilities required for release 4.0.
2. Operational experience led to the design and installation of several important reliability and performance enhancements.
3. Operational and user documentation was updated. This includes:

- MPM Commands
- MPM Subroutines
- MPM Reference Guide
- MPM SWG
- Multics Operator's Handbook
- Info segments
- SRB for 4.0

WORK COMPLETED

## 1. Statement of Problem.

MTB-017, November 1973. The Storage Problem

## 2. Design.

MTB-055, April 1974. Overview  
 MTB-060, May 1974. Paging Analysis  
 MTB-065, April 1974. New Bound on Performance  
 MTB-095, June 1974. Removable Disk Packs  
 MTB-110, August 1974. Implementation of New Storage System  
 MTB-167, February 1975. Disk Usage  
 MTB-203, June 1975. Attributes of Backup System  
 MTB-206, June 1975. SAVE and RESTOR  
 MTB-213, July 1975. Disk Definition  
 MTB-220, September 1975. Salvager  
 MTB-221, September 1975. Salvager Implementation  
 MTB-229, October 1975. Demountable Logical Volumes  
 MTB-233, November 1975. Backup  
 MTB-237, November 1975. Overview  
 MTB-238, November 1975. Initial MIT Installation  
 MTB-239, November 1975. Error Recovery  
 MTB-243, December 1975. User Ring Changes  
 MTB-246, December 1975. List Command  
 MTB-260, February 1976. Interim Mount  
 MTB-261, March 1976. Master Directory Control  
 MTB-266, March 1976. Removing DC from the Security Kernel

## 3. Task Schedules.

MTR-068, October 1974. Implementation Plans  
 MTR-081, March 1975. Long Range Plans  
 MTR-084, April 1975. Task List Phases I and II  
 MTR-095, September 1975. Long Range Plans  
 MTR-112, December 1975. Long Range Plans  
 MTR-119, March 1976. Long Range Plans  
 MTR-120, March 1976. Discussion of MTB-260  
 MTR-121, March 1976. Discussion of MTB-233  
 MTR-122, March 1976. Discussion of MTB-261

## 32a. Directory Control Checking.

This task adds to directory control new code for maintenance of the new directory fields. (See also task 32b.)

Installed in system 28-8.

## 37. Master Directory Operations.

This task adds ring-1 support for operations on master directories. User calls are create, delete and list. The

create\_dir and delete\_dir commands are modified for this case.

The ring-1 programs use the volume registration data base, access control segments, and the Master Directory Control Segments (MDCSs). Administrative commands to manage these data bases are provided. For the volume librarian, we need register, unregister, modify, and list.

Installed in system 28-4.

#### 38. Ring 1 Volume Mount Module (Interim).

When a logical volume is to be mounted the operator must type several commands to tell the system that the volumes are online. These commands check the volume label against the registration and when the volume is completely mounted call the hardware to cause the logical volume to be accepted for paging.

Installed in system 28-4.

#### 39. User Request to Connect Logical Volume (Interim).

User requests to connect to a logical volume will be passed through ring 1. If the user process is permitted to connect to the logical volume, and the logical volume is already mounted by the operator, the request is passed to the hardware.

Installed in system 28-4.

#### 40. Hardware Check on Volume Connection.

The hardware is changed by this task to require the connection call from ring 1 before allowing a process to initiate a segment on a demountable volume. (The root logical volume is never demountable and other "public" volumes can be declared not demountable.) This insures that ring 1 is not bypassed, and makes sure that all programs using segments on removable volumes execute independently of whether some other process has caused a pack to be mounted. The list of demountable physical volumes which the process is connected to will be stored in the KST.

Installed in system 28-4.

#### 41. Phase VI: Follow-up Installation at MIT.

Operational experience will lead us to make many improvements to the interface and behavior of the storage system. Performance measurements under actual load may also show use where to concentrate our programming effort in order to speed

the system up; if these improvements are possible we will install them soon.

Target date: March 1976.

Actual installation was spread over several systems.

#### 42. Command System Changes.

These changes are the ones specified in paragraph 27. In addition to the changes to handle new error and state conditions, the create\_dir command must accept and check the new parameter which specifies the logical volume in which storage will reside, and the status command must be modified to show this attribute.

Finished.

#### 43. Phase VII: Install MR 4.0 at MIT.

Target date: April 1976.

This installation was broken down into smaller parts, and was installed as follows:

28-1	3/19	fixes
28-2	4/01	fixes, speedups
28-4	4/26	mounting, registration
28-5	5/12	dismounting
28-7	6/10	reliability
28-8	6/16	reliability

### CURRENT TASKS

#### 44. Phase VIII: Release MR 4.0

Target Date: June 1976. Currently on schedule.

#### 52. Continuing Performance Improvement

This task includes the investigation and metering of the system's performance as installed at MIT, and the identification and removal of performance bottlenecks. For example, the locking and I/O strategies used by the supervisor will be studied. Some of the results of this investigation were included in systems 28-2, 28-4, and 28-5.

#### 24. Implementation of Hardcore Primitives for Backup.

The hardcore primitives to support the new backup system must be able to maintain the list of modified segments on each physical volume for the use of incremental dumping; and to activate and dump or reload a segment by volume ID and VTOC

Index without referencing the branch.

#### 25. Implementation of Backup Dumping Programs.

The new complete and incremental dumping programs can be much simpler than the current dump programs, since all hierarchy walking and access forcing code is eliminated. The hardcore primitives do most of the work. These programs are easy given the format of the output records to be produced.

#### 26. Implementation of New Reload and Retrieve.

The reloading and retrieval programs will use the output of the dumping programs to reconstruct volumes and to recover the contents of single segments.

#### 32b. Directory Control Checking.

This task adds to directory control new code for appropriate in-line checks of the new directory fields. MTB-220 describes the details of this change.

#### 53. Improve Disk DIM

This task covers improvements in several areas: handling of "device in standby" statuses, reassigning page addresses on error, and recording of bad track addresses.

#### 54. Connection Check while System is Running

The current method of performing a connection check from the VTOC back to the hierarchy requires complicated manipulations of disk packs and is error prone. This facility will be replaced by a privileged program which runs under Multics and which can collect free VTOC entries while the system is using the volume.

#### 55. Volume Maintenance Programs

This step provides utilities for moving segments from one physical volume to another upon (privileged) request. This facility can be used to compress a logical volume. A facility to grow or shrink partitions and VTOCs will also be provided.

#### 56. Salvager Improvements

This step rewrites the directory salvager to operate in a cleaner and more reliable fashion. We hope that we will be able to permit users to invoke the on-line salvager to cause a directory to be compacted via hcs\_.

**57. Enforce Directory Quota**

Directory quota is not currently enforced, and a determined user could cause system problems by creating many directory records. When users can control their usage (i.e. when they can compact directories on demand) and when the system is known to function correctly even when a directory cannot be expanded, the call side of directory control will be modified to enforce the directory quota.

EURIHER ENHANCEMENTS

## 36. Backup Integration.

This task integrates the new backup mechanisms into the system and ties backup in with salvaging.

Although most of the parts of the new backup system will be available by the time release 4.0 is frozen, the new backup has not had sufficient testing and operational experience to allow us to depend upon it.

## 51. Change Volume Mounting to use RCP.

Modify the mount and demount commands to use RCP for mounting and demounting volumes.

When a logical volume is to be mounted, the LVRF must be consulted to find the list of physical volumes to be mounted. Calls must then be made to RCP to mount each of the physical volumes, the volume labels must be checked, and the hardware must be called to tell it that the volumes are accepted.

## 46. Keep Duplicate Copies of Selected Volumes.

Once this task is completed, crucial volumes in the system can be maintained in duplicate; all modified pages will be written out to both devices. In a configuration which places the secondary copy on a different disk subsystem from the primary copy, the cost of maintaining two copies will be very low.

## 47. Automatic Use of Secondary Volume on Error.

Once the duplicate copy facility is available, the system can be modified so that when a disk record is unreadable, the system automatically switches to the use of the secondary copy.

## 49. Calls to Initializer Process During Connection.

This step causes RCP to pass all connection requests through the system control process, so that charging can be done, mount messages can be routed, and so that operator commands affecting the request can be issued.

## 50. Billing.

Modifications must be made to the administrative and billing package to enhance the administrator's ability to manage the system resources. Some of these improvements cannot be specified until we have obtained some operational experience.
